PREFACE

GASTROENTEROLOGY ABSTRACTS and CITATIONS is a publication of the National Institute of Arthritis, Metabolism and Digestive Diseases. This specialized information medium has been initiated to fill an existing great need in the field of gastroenterology and to assist the Institute in meeting its obligations to foster and support laboratory and clinical research into the nature, causes, and therapy of diseases of the gastrointestinal tract. Publication GASTROENTEROLOGY ABSTRACTS and CITATIONS makes available citations of all current papers relevant to this field from medical journals published throughout the world. Approximately one-third of the citations dealing with the major aspects of gastroenterology have accompanying abstracts.

The issuing of GASTROENTEROLOGY ABSTRACTS and CITATIONS under the auspices of the National Institute of Arthritis, Metabolism, and Digestive Diseases will provide a much needed current awareness tool to scientists and will facilitate greater integration of research and clinical efforts in this field. The number and great diversity of publications in the area of gastroenterology makes it imperative that an appropriate service be available to investigators and practitioners so that they may be apprised of progress with a minimum of delay. Our aim is to provide the readers with a readily systematized compilation of current published work. The publication will provide the greatest usefulness if these interested investigators will contribute their ideas and comments for consideration whenever possible.

GASTROENTEROLOGY ABSTRACTS and CITATIONS is published monthly and includes citations and abstracts from the biomedical world literature as they are currently received. In addition, yearly cumulated subject and author indexes are published.

This publication is available free to National Institutes of Health grantees and contractors working in the field of gastroenterology and libraries of medical schools. Requests from these qualified individuals to receive free copies of this publication must include their grant or contract number and the title of their project. These requests as well as address changes and other communications should be addressed to:

Scientific Communications Officer
Gastroenterology Abstracts and Citations
National Institute of Arthritis, Metabolism and Digestive Diseases
National Institutes of Health
Building 31, Room 9A-21
Bethesda, Maryland 20014

Other individuals and libraries may receive this publication by subscribing *directly* to the Superintendent of Documents, U.S. Government Printing Office, Washington, D.C. 20402. Subscription price per year in the United States and its possessions: $27.00 (this includes index issue); foreign, $6.75 additional. Single copy price is $1.90 domestic and $2.40 foreign. The index issue is $3.45 domestic and $4.35 foreign. Payment is required in advance, and check or money order should be made payable to the Superintendent of Documents.

The Secretary of the Department of Health, Education, and Welfare has determined that the publication of this periodical is necessary in the transaction of the public business required by law of this Department. Use of funds for printing this periodical has been approved by the Director of the Office of Management and Budget through April 30, 1981.

For sale by the Superintendent of Documents, U.S. Government Printing Office, Washington, D.C. 20402. Subscription price per year in the United States and its possessions: $27.00 (this includes index issue); foreign, $6.75 additional. Single copy price is $1.90 domestic and $2.40 foreign. The index issue is $3.45 domestic and $4.35 foreign. Payment is required in advance, and check or money order should be made payable to the Superintendent of Documents.

NOTE

Journal names are abbreviated according to the list of abbreviations used by *Index Medicus*. For journals not covered by *Index Medicus*, the abbreviations (with some modifications) found in *International Standard ISO833, 1974*, are used. The two-letter state abbreviations are based on the United States Postal Service Code.

PRE-CLINICAL SCIENCES

MORPHOLOGY, CELLULAR STRUCTURE AND HISTOCHEMISTRY

0001 AN ULTRASTRUCTURAL STUDY OF OSMIOPHILIA IN NORMAL HUMAN OESOPHAGEAL EPITHELIUM.

(Eng.) Logan, K. R.; Milne, G.; Hopwood, D. (Ninewells Hosp. and Medical Sch., Dundee, DD2, 1UB, Scotland). *Histochemistry* 53(2):183-187; 1977.

The forming face of the Golgi stack was studied in biopsy specimens of normal human esophagus, using the prolonged osmication technique. The forming face of the Golgi apparatus was demonstrated in the basal and lower prickle cells. These cells also showed osmium deposition in their mitochondria, endoplasmic reticulum, perinuclear cisternae, and lysosomes. The capillary endothelial cells also showed osmium deposition in their Golgi apparatus and endoplasmic reticulum. These studies suggest that the Golgi apparatus may be involved in forming membrane coating granules, similar to those previously described in skin, vagina, and buccal mucosa.

0002 DISTRIBUTION, ONTOGENY AND ULTRASTRUCTURE OF THE MAMMALIAN SECRETIN CELL.

(Eng.) Larsson, L. I.; Sundler, F.; Alumets, J.; Hakanson, R.; Schaffalitzky de Muckadell, O. B.; Fahrenkrug, J. (Inst. Medical Biochemistry, Univ. Aarhus, DK-8000 Aarhus C, Denmark). *Cell Tissue Res.* 181(3):361-368; 1977.

Secretin cells were studied immunocytochemically in adult rats, cats, pigs, and man, and in fetal and young rat tissues. Secretin cells were demonstrated in the duodenum and jejunum of all species. Calculations on the relative frequency of such cells indicate that the bulk of secretin occurs in the jejunum, which supports the view that secretin may be released by physiological stimulants other than hydrochloric acid. Ultrastructural identification of cat and pig secretin cells confirmed their identity with the ultrastructurally defined S cells, and staining experiments revealed that secretin cells were argyrophilic. Secretin cells were detected in the 17-day-old fetal rat duodenum and showed a developmental pattern similar to that displayed by gastrin cells. Secretin may play a role in the early regulation of growth of the fetal gastrointestinal tract.

0003 MORPHOLOGICAL CHANGES IN THE SMALL INTESTINE FOLLOWING JEJUNO-ILEAL SHUNT IN PARENTERALLY FED RATS.

(Eng.) Fenyo, G.; Hallberg, D.; Soda, M.; Roos, K. A. (Karolinska sjukhuset, Stockholm, Sweden). *Scand. J. Gastroenterol.* 11(6):635-640; 1976.

The importance of the presence of food in the intestinal lumen during adaptation to diminished intestinal absorptive surface was studied in rats undergoing a jejuno-ileal bypass (85% of the small intestine excluded) and in sham-operated rats. Body weights of sham-operated and shunt-operated rats fed p.o. with pellets were 151 ± 2.8 and 151 ± 22 g, resp., at the time of surgery and 231 ± 4.1 and 156 ± 4.3 g, resp., 2 weeks after operation. Sham- and shunt-operated rats given total parenteral nutrition (TPN) had body weights of 157 ± 1.6 and 161 ± 8.2 g, resp., at the time of operation and 206 ± 7.5 and 192 ± 8.3 g, resp., 2 weeks after operation. The weight differences were significant at 2 weeks after surgery between pellet-fed, sham-, and shunt-operated rats ($p<0.001$) and between pellet fed and TPN rats in both surgical groups. The functioning part of the small intestine of shunt-operated rats was hypertrophic in both p.o. and TPN fed rats in comparison with sham-operated rats with the corresponding nutrition. When intestinal wet and dry weight per 3-cm intestine were determined from five small intestinal segments 2 weeks after operation, both p.o. and TPN nourished shunt-operated rats showed significantly ($p<0.05$ or less in all cases) increased wet and dry weights in all segments except the top of the blind loop where there was a significant decrease ($p<0.001$) for p.o. fed rats and no significant change for TPN nourished rats. Villus height in both p.o. and TPN nourished shunt-operated rats was significantly ($p<0.01$ or less in all cases) increased in all segments but the top of the blind loop (no significant change) compared with the villus height of sham-operated controls. The absolute villus height was significantly ($p<0.05$ or less) greater in p.o. fed rats than in TPN nourished rats in each surgical group. The percentage differences in villus height between shunt- and sham-operated rats were higher in the TPN group than in p.o. fed rats. The results demonstrate that rats with adequate parenteral nutrition 2 weeks after 85% small intestinal bypass develop hypertrophic changes of the intestinal mucosa, indicating the existence of a nonfood-dependent mechanism in the development of adaptive mucosa changes. Nevertheless, the presence of food seems to stimulate quantitatively greater hypertrophic changes.

0004 FUNCTIONAL ALTERATIONS OF LIVER MITOCHONDRIA IN CHRONIC EXPERIMENTAL ALCOHOLISM.

(Eng.) Koch, O. R.; Bedetti, C. D.; Gamboni, M. (Facultad de Medicina, Universidad de Buenos Aires, J. E. Uriburu 950, Buenos Aires, Argentina). *Exp. Mol. Pathol.* 25(3):253-262; 1976.

Morphologic and functional alterations of mitochondria obtained from nonfatty livers of male rats fed a super diet (vitamin and lipotrope-enriched) for 4 months which included a 25% sucrose-32% ethanol mixture (group A), were compared with mitochondrial alterations observed in the livers of three control groups of rats. In the control groups, alcohol was isocalorically replaced by sucrose (group B), by fat (group C), or by a basal diet (group D). Livers from group A rats showed fatty changes similar to those seen in livers of the control groups of rats. However, numerous megamitochondria were observed in group A livers; their preferential hepatocytic lobular location was in midzonal areas, although they were also found in centrilobular hepatocytes. In control livers, the hepatocytes predominantly affected were in periportal areas, and no megamitochondria were observed. Ultrastructurally, group A enlarged mitochondria displayed bizarre shapes. Their cristae were diminished in number, and helical filaments were occasionally observed in dilated cristae and/or in the outer mitochondrial space. The ultrastructural configuration of hepatocytes from control groups B, C, and D was normal. Maximum mitochondrial respiration rate (ng-atoms of oxygen/min/mg protein) in group A rats was significantly lower ($p < 0.001$, 83 ± 27) than that for group B (176 ± 16), group C (163 ± 28), and group D (159 ± 31) rats when succinate (10 mM) was used as substrate. A similar pattern was observed when L-malate (5 mM)-L-glutamate (5 mM) was used as substrate ($p < 0.001$). When β-hydroxybutyrate (5 mM) was used as substrate, the maximal mitochondrial respiration rate of group A rats (45 ± 9) was significantly ($p < 0.05$) lower than that of group B (61 ± 9) and group C (59 ± 12) rats but not significantly different from that of group D rats (57 ± 15). When succinate or malate-glutamate was used as substrate, the coupling of oxidative phosphorylation in group A rats was similar to that of controls, but with β-hydroxybutyrate a small reduction in coupling was noted in group A rats compared with group B and C rats ($p < 0.02$). These results suggest that hepatic mitochondrial respiration is significantly altered when ethanol is supplied to rats at high levels over long periods and when a nutritional basal diet that does not induce fatty liver is used.

0005 ULTRASTRUCTURAL CYTOCHEMISTRY OF THE SECRETORY GRANULES OF THE HAMSTER SUBMANDIBULAR GLAND. (Eng.) Bloom, G. D.; Carlsoo, B.; Danielsson, A.; Wahlin, T. (Dept. Histology, Univ. Umea, S-90187, Umea, Sweden). *Histochemistry* 51(4):261-268; 1977.

The ultrastructure and cytochemistry of the secretory granules of the male hamster submandibular salivary gland were studied. After fixation in glutaraldehyde followed by osmium tetroxide, the granules were seen to exhibit a characteristic bipartite substructure, with an electron lucid crescenteric rim and a more dense central core. Two regions of the granules were visualized in specimens primarily fixed in Millonig's osmium tetroxide or in potassium permanganate. The electron lucid peripheral portion of the membrane bounded secretory granules further displayed a strong positive reaction after staining of ultrathin sections with the periodic acid-chromic acid-(PA-CrA)-silver technique. The strong periodate reactivity of the rim relative to the core suggested a difference in mucin composition of the two granule regions. With the PA-CrA-silver staining technique, a positive reaction was also observed within the Golgi apparatus of the acinar cells.

0006 QUANTITATIVE AGE CHANGES IN THE HISTOLOGICAL STRUCTURE OF HUMAN SUBMANDIBULAR SALIVARY GLANDS. (Eng.) Scott, J. (Univ. Liverpool, Pembroke Place, P.O. Box 147, Liverpool, L69 3BX, England). *Arch. Oral Biol.* 22(3):221-227; 1977.

The nature, extent, and rate of age-related volumetric tissue changes were examined in human submandibular salivary glands. The glands were obtained from a series of 96 necropsies evenly representative of sex and all decades between 16 and 95 yr. With increasing age, the volume of parenchyma steadily lessened ($p < 0.001$) while the proportions of other tissues rose; this effect was due mainly to loss of acinar tissue, as the volume of ducts underwent a gradual net increase with increasing age. There was an acceleration in the rates of volumetric tissue changes in the two final decades of life. A progressive increase in vascular volume was related to increasing levels of degenerative vascular disease that may, through ischemia, bear some causal relation to the ageing atrophy of parenchyma. The rates of ageing changes were similar in each sex.

0007 AFFERENT ACTIVITY OF THE STOMACH VAGAL AND SYMPATHETIC PATHWAYS IN RELATION TO THERMAL EFFECTS ON ITS WALLS. (Rus.) Nozdratchev, A. D.; Pulatova, M. D.; Tersunov, Z. T.; Chubarova, N. I. (Pavlov's Inst. Physiology, Acad. Science USSR, Leningrad, USSR). *Fiziol. Zh. SSSR* 63(6):896-903; 1977.

0008 ENDOCRINE CELLS OF THE GUT. II. DISTRIBUTION AND THE BASIS FOR ULTRASTRUCTURAL IDENTIFICATION. (Pol.) Mirecka, J. (Z Zakladu Histologii IBM AM, Cracow, Poland). *Przegl. Lek.* 34(4):419-422; 1977.

0009 COMPARATIVE RADIOLOGICAL AND MORPHOLOGICAL STUDY OF THE HUMAN PANCREAS. 2. MORPHOMETRIC INVESTIGATION OF THE HUMAN PANCREATIC DUCT SYSTEM. (Ger.) Schmitz-Moormann, P.; Hein, J.; Thoma, W.; Ihm, P. (Pathologisches Institut der Universitat Marburg, D-3550 Marburg/Lahn, W. Germany). *Anat. Anz.* 141(5):507-511; 1977.

0010 PECULIARITIES OF THE VENOUS BED HISTOLOGY IN THE HEMORRHOIDAL ZONE OF HUMAN RECTUM. (Rus.) Melman, E. P.; Datsun, I. G. (Ivano-Frankovsk Medical Inst., Ivan-Frankovsk, USSR). *Arkh. Anat. Gistol. Embriol.* 73(8):59-65; 1977.

0011 OCCURRENCE OF PSEUDOISOCYANINE-POSITIVE ENDOCRINE CELLS IN THE MIDGUT OF THE HAMSTER (Cricetulus griseus). (Ger.) Hahn von Dorsche, H.; Hartelt, E.; Fehrmann, P.; Krause, R. (Anatomisches Institut der Ernst-Moritz-Arndt-Universitat Greifswald, Friedrich-Loeffler Strasse 23c, DDR-22 Greifswald, E. Germany). *Acta Histochem.* 59(1):168-171; 1977.

0012 CONSTRUCTION OF MILLIGAN AND MORGAN'S ANORECTAL RING. (Spa.) Gomez Oliveros, L.; Forcada Jimenez, M. (Facultad de Medicina, Universidad Complutense de Madrid, Madrid, Spain). *Rev. Esp. Enferm. Apar. Dig.* 50(4):377-390; 1977.

0013 EVOLUTIONARY CHANGES IN THE ESOPHAGEAL LINING OF VERTEBRATES AND MAN IN THE LIGHT OF THE PHYLEMBRYOGENESIS THEORY. (Rus.) Bazhanov, A. N. (Tselinograd Medical Inst., Tselinograd, USSR). *Arkh. Anat. Gistol. Embriol.* 71(10):61-67; 1976.

0014 HISTOLOGICAL AND ULTRASTRUCTURAL STUDIES OF THE ISOLATION OF RAT SMALL INTESTINE EPITHELIAL CELLS. (Ita.) Cusaro, G.; Marchetti, C.; Poggi, P. (Istituto di Fisiologia umana, Universita di Pavia, Pavia, Italy). *Boll. Soc. Ital. Biol. Sper.* 52(5):371-377; 1976.

0015 THE ULTRASTRUCTURE OF ENTEROCYTES OF THE UPPER PART OF THE MOUSE SMALL INTESTINAL VILLI. (Rus.) Parshkov, E. M.; Brodsky, R. A.; Pogudina, N. A. (Inst. Medical Radiology, Acad. Medical Sciences USSR, Obninsk, USSR). *Tsitologiia* 18(11):1393-1394; 1976.

0016 MORPHO-FUNCTIONAL PECULIARITIES OF THE ENDOCRINE CELLS OF THE SMALL INTESTINE IN CHILDREN. (Rus.) Gavalov, S. M.; Korostyshevskaya, I. M.; Vinogradova, M. S.; Yakovleva, V. I. (Inst. Cytology and Genetics, Siberian Branch of USSR Acad. Sciences, Novosibirsk, USSR). *Vopr. Okhr. Materin. Det.* 21(9):23-28; 1976.

ABSORPTION - EXCRETION - TRANSPORT

0017 INCREASE IN HUMAN INTESTINAL PERMEABILITY FOLLOWING INGESTION OF HYPERTONIC SOLUTIONS. (Eng.) Laker, M. F.; Menziew, I. S. (St. Thomas' Hosp. Medical Sch., Lambeth Palace Rd., London SE1 7EH, England). *J. Physiol. (Lond.)* 265(3):881-894; 1977.

A simple oral loading technique was used to investigate the intestinal permeability of 21 healthy adults following the ingestion of lactulose (L) solutions made hypertonic by the addition of several solutes. The subjects were given 100 ml of a solution containing 5 g L and 20, 40, or 60 g sucrose. Some of these subjects were also tested with L solutions containing 30 g glucose, 12 g glycerol, or 22 g mannitol. The different solutions were given to the subjects in varied order, and there was a 3-day interval between tests. After each test, the urine was collected for 5 hr, and the amount of L excreted was quantitated by paper chromatography. The 5-hr L excretions after ingestion of an L solution without sucrose (isotonic control) were 10-30 mg (median, 15). They rose to 11-50 mg (median, 17) after 20 g sucrose, 8-127 mg (19) after 40 g sucrose, and 12-134 mg (33) after 60 g sucrose. Analysis of variance calculations showed a significant regression ($p<0.01$). Eighteen of the subjects received the glucose-containing loads, and they excreted 13-172 mg (median, 41) L. The amount of L excreted over 5 hr from four subjects given the mannitol loads was 8.9, 9.5, 8.9, and 62.5 mg; these same subjects excreted 31.7, 18.8, 17.0, and 78.5 mg L, resp., after the glycerol loads. The responses of individual subjects were reproducible and consistent. Those with high L excretion following hypertonic sucrose loads responded similarly following glucose, mannitol, and glycerol loads; those with low L transfer also behaved consistently. Intestinal permeability to L is enhanced as the solute concentration is increased, probably as a result of the increased L absorption from the intestinal lumen induced by the hypertonic solutions.

0018 EFFECT OF SEROTONIN TREATMENT ON INTESTINAL TRANSPORT IN THE RABBIT. (Eng.) Donowitz, M.; Charney, A. N.; Heffernan, J. M. (Walter Reed Army Inst. Res., Washington, DC 20012). *Am. J. Physiol.* 232(1):E85-E94; 1977.

To determine whether serotonin is an intestinal secretagogue and thus the cause of diarrhea in the carcinoid syndrome, the effect of serotonin on intestinal water and electrolyte transport was evaluated in rabbits. Two weeks of daily s.c. injection of serotonin (52 μmol/kg) suspended in oil resulted in a blood serotonin level elevated to twice that of controls. Intestinal transport was studied *in vivo* by a perfusion technique. Serotonin treatment resulted in ileal secretion and decreased mid-jejunal absorption of water and electrolytes, but did not affect water absorption in the proximal jejunum or colon. Intestinal absorption of D-glucose and the amino acid L-tryptophan and glucose-dependent water and electrolyte absorption were normal in serotonin-treated animals. Serotonin-induced ileal secretion was reversed by methysergide, a peripheral antagonist of serotonin action. No alterations in intestinal histology or permeability occurred in serotonin-treated animals. Serotonin-induced intestinal secretion was not associated with alterations in the activities of intestinal mucosal adenylate cyclase, cyclic nucleotide phosphodiesterase, or Na-K-ATPase. This rabbit model for serotonin-induced intestinal water and electrolyte secretion has many characteristics similar to those in patients with the carcinoid syndrome and diarrhea. Both exhibit blood serotonin levels elevated to at least twice normal levels, net intestinal secretion or decreased net absorption of water and electrolytes, reversal of net intestinal secretion to net absorption by methysergide treatment, normal intestinal glucose absorption, and normal glucose-dependent intestinal water and electrolyte absorption with conversion by luminal glucose of net intestinal secretion of water into net absorption.

0019 EFFECTS OF VASOACTIVE INTESTINAL PEPTIDE, SECRETIN, AND RELATED PEPTIDES ON RAT COLONIC TRANSPORT AND ADENYLATE CYCLASE ACTIVITY.

(Eng.) Waldman, D. B.; Gardner, J. D.; Zfass, A. M.; Makhlouf, G. M. (Medical Coll. Virginia, Richmond, VA 23298). *Gastroenterology* 73(3):518-523; 1977.

Vasoactive intestinal peptide (VIP), secretin, glucagon, gastric inhibitory peptide (GIP), and partial sequences of VIP and secretin were examined for their effect on colonic transport and adenylate cyclase activity in male Sprague-Dawley rats. Net water flow was measured gravimetrically in muscle-stripped, everted sacs of ascending and descending colon. VIP and secretin, but not glucagon or GIP, stimulated colonic secretion. The sensitivity of the colonic mucosa to VIP was high; the threshold (10^{-11} M) and half-maximal dose (10^{-10} M) for the effect of VIP were 1,000 times less than the threshold (10^{-8} M) and half-maximal dose (10^{-7} M) for the effect of secretin. A subthreshold concentration of theophylline (2 mM) increased the submaximal responses to VIP or secretin up to but not beyond the maximal response to VIP alone (4.1 ± 0.2 μl/mg/30 min). The combined effect of secretin and a maximal concentration of VIP was not additive. These results indicate that VIP and secretin share the same receptor sites and/or intermediary mechanisms. VIP$_{14-28}$ acted as a partial agonist with an efficacy of 0.2 and significantly inhibited the response to VIP. Secretin$_{5-27}$ showed no secretory activity and did not inhibit the response to secretin. The lactamimide RMI 12330A (10^{-3} M) abolished the secretory response to VIP and secretin but had no effect on the secretory response to 10 mM theophylline or on control absorptive flow rate. VIP and secretin, but not glucagon or GIP, stimulated adenylate cyclase activity in homogenates of colon mucosa. The lactamimide RMI 12330A (10^{-3} M) inhibited basal adenylate cyclase activity as well as activity stimulated by VIP, secretin, prostaglandin E$_1$ and 5'-guanylyl imidodiphosphate. The results obtained in colon mucosa conform to a pattern of structural and functional homology exhibited by VIP and secretin in several tissues (fat, liver, and pancreatic acinar cells), which sets them apart from glucagon and GIP. The mode of action of VIP and secretin on colonic secretion appears to involve the adenylate cyclase-cylic AMP system. The abundance of VIP in the colon of many species and the high sensitivity of transport mechanisms to VIP raise the possibility that VIP may play a local (i.e., paracrine and/or neurocrine) role in the regulation of colonic transport.

0020 THE KINETICS OF ETHANOL ABSORPTION AND ELIMINATION IN TWINS AND SUPPLEMENTARY REPETITIVE EXPERIMENTS IN SINGLETON SUBJECTS.

(Eng.) Kopun, M.; Propping, P. (Institut fur Zellforschung am Deutschen Krebsforschungszentrum, P.O. Box 10149, D-6900 Heidelberg, W. Germany). *Eur. J. Clin. Pharmacol.* 11(5):337-344; 1977.

The influence of genetic and environmental factors on the metabolism of a single p.o. dose of ethanol (1.2 ml/kg) was analyzed in 19 identical and 21 fraternal healthy, adult, un-selected male twins. The heritability values of the rates of absorption, degradation, and elimination of ethanol were 0.57, 0.41, and 0.46, resp. Environmental factors, such as daily alcohol intake and smoking, increased the rate of elimination of blood alcohol. Intrasubject variation in ethanol metabolism was studied by repeated tests in 11 male volunteers at intervals of at least 2 months, under the same conditions as in the twins; the coefficient of variation for parameters of metabolism was about 8%. The results demonstrate both genetic control of ethanol absorption, degradation, and elimination and the appreciable influence of environmental factors. The almost total genetic control of ethanol metabolism, which was postulated previously, could not be confirmed.

0021 ALTERATIONS IN THE ENDOPLASMIC RETICULUM AND GOLGI COMPLEX OF INTESTINAL EPITHELIAL CELLS DURING FAT ABSORPTION AND AFTER TERMINATION OF THIS PROCESS: A MORPHOLOGICAL AND MORPHOMETRIC STUDY.

(Eng.) Friedman, H. I.; Cardell, R. R. (Dept. Surgery, Letterman Army Inst. Res., Presidio of San Francisco, CA 94129). *Anat. Rec.* 188(1):77-102; 1977.

The morphological changes in the endoplasmic reticulum (ER) and Golgi complex during fat absorption and at successive time intervals after the termination of fat absorption were studied in male rats. Following the administration of corn oil by intubation, the smooth endoplasmic reticulum (SER) was seen to proliferate, and numerous vesicles contained reesterified lipid. The rough endoplasmic reticulum (RER) decreased, and 1 hr after fat administration, the RER only occupied a narrow zone interposed between the Golgi complex and the SER region. These findings were confirmed by morphometric analysis; the RER decreased from approximately 2.4 to 1.2 μ/μ^2 cytoplasm, while the SER increased from approximately 3.7 to 4.8 μ/μ^2 cytoplasm, from the fasted to the fat-fed state ($p<0.01$). The Golgi complex was seen to accumulate lipid in the Golgi vacuoles after fat administration. Lipid droplets did not occur in saccules near the forming face of the Golgi complex, and as the absorptive process continued, the length and number of Golgi saccules decreased significantly (by 0.74 μ of membrane/μ^2 cytoplasm) from the fasted state to 60 min after fat administration ($p<0.01$). The Golgi vacuoles increased by 0.32 μ of membrane/μ^2 cytoplasm ($p<0.01$). After the termination of fat absorption, using a saline flush, the RER progressively increased, and the quantity of SER lipid-containing vesicles decreased. The Golgi vacuoles decreased in number and size, while the saccules increased in length and number after the termination of fat absorption. The results support the suggestion that during fat absorption, membrane synthesis by the RER is insufficient to accomodate membrane utilization and intraconversion, resulting in a decrease of both ER and Golgi complex components. Following the termination of fat absorption, the cell is able to replace previously depleted components of the ER and Golgi complex and regain the full membrane complement of the fasted state. Replenishment of cellular membranes may result from a continued synthesis of new membranes by the RER, which eventually exceeds the amount membrane utilized during lipid transport.

0022 IRON ABSORPTION IN THE RAT: THE SEARCH FOR POSSIBLE INTESTINAL MUCOSAL CARRIERS.

(Eng.) Halliday, J. W.; Powell, L. W.; Mack, U. (Royal Brisbane Hosp., Brisbane 4029, Australia). *Br. J. Haematol.* 34(2):237-250; 1976.

The biological relevance of four iron-containing fractions previously detected in rat intestinal mucosal cells was studied. The distribution of iron in these fractions, obtained by chromatography on Sepharose 6B, was examined after *in vivo* and *in vitro* incubation of mucosal cells with ^{59}Fe. In addition, the effects of phenobarbitone, cycloheximide, iron-deficiency, and iron-loading on the uptake and distribution of iron within the four mucosal cell fractions was studied. The iron in fraction I was mostly bound to intracellular membrane particles. Fraction II was shown to be ferritin. Fraction III contained some transferrin and also a protein of molecular weight similar to transferrin, but which was not precipitable by antitransferrin antiserum. Under all experimental conditions (normal, iron-loaded, iron-deficient, phenobarbitone- and cycloheximide-treated animals) fraction I contained less ^{59}Fe in the *in vivo* than in the *in vitro* studies. In iron deficiency, the ^{59}Fe/protein ratio in fractions I and III was markedly increased, especially *in vivo*, and fraction II (ferritin) was not detectable either by agar gel diffusion or polyacrylamide gel electrophoresis. In iron-loaded animals, the ^{59}Fe/protein ratio was increased in fraction II. Cycloheximide treatment resulted in a decrease in the ^{59}Fe content of fraction I, but not in the other fractions. Phenobarbitone treatment produced no detectable change in any fraction. Quantitative differences between the *in vivo* and *in vitro* studies combined with the results of "chaser" experiments suggested that, in addition to ferritin, at least two fractions (I and III) were involved in the process of iron absorption by the mucosal cells.

0023 Na AND Cl TRANSPORT AND SHORT-CIRCUIT CURRENT IN RABBIT ILEUM.

(Eng.) Tai, Y. H.; Desjeux, J. F.; Danisi, G.; Curran, P. F. (Walter Reed Army Medical Center, Washington, DC 20012). *J. Membr. Biol.* 31(1/2):189-208; 1977.

Na and Cl fluxes and short-circuit current (I_{sc}) in rabbit ileum were studied as a function of ionic concentrations in HCO$_3$-free solutions. Both net Na flux (J^{Na}_{net}) and I_{sc} showed similar saturation functions of [Na] at fixed [Cl]. They showed no significant difference between 0 and 112 mM Na, but at 140 mM Na I_{sc} was significantly greater than the J^{Na}_{net}. Net Cl transport (secretion) was observed only at 140 mM Na and was approximately equivalent to the difference between the I_{sc} and J^{Na}_{net}. The transcellular mucosa-to-serosa Na fluxes measured at 140 and 70 mM Na did not differ significantly from the corresponding I_{sc}. The net Cl flux varied with [Cl] at fixed [Na], but I_{sc} was virtually not affected by [Cl]. These results suggest that the absorptive Na transport process is electrogenic and responsible for the I_{sc} and that the secretory fluxes of Na and Cl are coupled, require high [Na], vary with [Cl], and do not contribute to I_{sc}. A K-free solution abolished the I_{sc} after a prolonged lag. The intracellular Na and K concentrations did not vary significantly with anion concentration. All Cl-containing solutions gave approximately the same intracellular Cl concentration, but the Cl-free solutions gave about 10 mM inexchangeable or slowly exchangeable Cl.

0024 INHIBITION OF ION TRANSPORT BY BILE SALTS IN CANINE GASTRIC MUCOSA.

(Eng.) Kuo, Y. J.; Shanbour, L. L. (Univ. Texas Medical Sch., Houston, TX 77025). *Am. J. Physiol.* 231(5):1433-1437; 1976.

The effect of bile salts on ion transport was studied in *in vivo* and *in vitro* canine stomach preparations. The instillation of 5, 10, and 20 mM of bile salts in *N*-tris(hydroxymethyl)methyl-2-aminoethane sulfonic acid buffered to pH 7.4 by NaOH into the nonsecreting stomach *in vivo* caused a progressive decrease in electrical potential difference (PD) and an increase in electrical resistance (R). The rate of acid secretion, determined by the pH-stat method in the histamine-stimulated stomach, decreased with 5 and 20 mM of bile salts. Mucosal ATP content of the nonsecreting or secreting stomach was reduced by bile salts. *In vitro* flux studies demonstrated that within the first hour after 1 mM of bile salts were added to the mucosal side of the chamber, PD decreased, R increased, and net sodium transport decreased. In the second hour, unidirectional fluxes of sodium increased, indicating an increase in permeability of the gastric mucosa to sodium. These results demonstrate that the initial action of bile salts is inhibition of ion transport, which is followed by an increase in permeability.

0025 ABSORPTION OF AMINO PENICILLINS FROM EVERTED RAT INTESTINE. (Eng.) Dixon, C.; Mizen, L. W. (Beecham Pharmaceuticals, Brockham Park, Betchworth, Surrey, RH3 7AJ, England). *J. Physiol. (Lond.)* 269(3):549-559; 1977.

The absorption of the amino penicillins amoxycillin, ampicillin, cyclacillin, BRL 11792, BRL 10351, BRL 8033, BRL 8035, and BRL 7116 was studied in rat jejunum, using an *in vitro* everted gut sac method to identify the involvement of any specialized transport mechanisms in their absorption across the intestine. Only cyclacillin (1-amino-cyclohexyl penicillin) was shown to be actively transported. The other penicillins appeared to diffuse passively across the intestine. Cyclacillin was found to concentrate against a gradient at 37 C but not at 19 C. Transport of cyclacillin across the mucosal membrane was saturated at mucosal concentrations greater than 1,000 μg/ml. The rate of the forward flux of cyclacillin was many times that of its back flux, the latter being detectable only after 30 min. No relationship between the active transport of cyclacillin and that of amino acids could be demonstrated.

0026 ENERGY-RICH PHOSPHATES AND TRANSINTESTINAL TRANSPORT IN RAT INTESTINE INCUBATED IN VITRO AT DIFFERENT TEMPERATURES. (Eng.) Faelli, A.; Esposito, G.; Capraro, V. (Istituto di Fisiologia Generale e di Chimica Biologica, State Univ. Milan, Milan, Italy). *Biochim. Biophys. Acta* 455(3):759-766; 1976.

Tissue levels of ATP, ADP, and AMP were measured in everted rat jejunum incubated *in vitro* at 28 and 38 C for 1 hr and were compared with levels observed *in vivo* in unperfused (control) jejunum to investigate factors affecting intestinal fluid transport *in vitro*. Intestinal fluid transport values of 2.20 ± 0.24 and 0.98 ± 0.24 mg/g total dry weight intestine/hr were measured for intestines perfused *in vitro* for 1 hr at 28 and 38 C, resp.; these differences were significant ($p<0.01$). A comparison of wet/dry weight ratios of *in vitro* perfused intestinal mucosa scrapes and the remaining submucosa (at both incubation temperatures) with wet/dry weight ratios of *in vivo* unperfused control mucosa and submucosa revealed mucosal swelling under *in vitro* conditions at both temperatures ($p<0.01$ at 28 C and $p<0.001$ at 38 C); swelling was greater at 38 C. Additional fluid transport measurements made every 20 min during *in vitro* intestinal perfusion for 1 hr at 28 and 38 C revealed that fluid transport was constant throughout the 1-hr perfusion period at 28 C but progressively decreased with time at 38 C. ATP levels in total intestine and mucosal scrapes at the beginning of perfusion at 28 C were reduced from control (*in vivo*) values of 7.6 ± 0.6 and 6.7 ± 0.7 μmol/g, resp., to 3.7 ± 0.4 and 4.4 ± 0.3 μmol/g, resp. After 1 hr of perfusion at 28 C, these levels remained fairly constant, being 3.8 ± 0.3 and 3.8 ± 0.4 μmol/g, resp. However, ATP levels in total intestine and mucosal scrapes perfused at 38 C fell from values of 2.4 ± 0.4 and 1.9 ± 0.5 μmol/g, resp., recorded at the beginning of perfusion, to levels of 0.8 ± 0.1 and 0.4 ± 0.1 μmol/g, resp., after 1 hr of perfusion. A similar trend was seen for ADP. AMP levels under the above conditions did not vary appreciably. These results indicate that fluid transport and ATP content of *in vitro* perfused intestine are directly related. Transport activity, which is lower at 38 C than at 28 C, appears to be due to a low availability of energy-rich phosphates.

0027 ROLE OF 1,25-DIHYDROXYVITAMIN D_3 ON INTESTINAL PHOSPHATE ABSORPTION IN RATS WITH A NORMAL VITAMIN D SUPPLY. (Eng.) Rizzoli, R.; Fleisch, H.; Bonjour, J. P. (Dept. Pathophysiology, Univ. Berne, 3010 Berne, Switzerland). *J. Clin. Invest.* 60(3):639-647; 1977.

The question of whether changes in 1,25-dihydroxyvitamin D_3 [$1,25\text{-(OH)}_2D_3$] production can influence intestinal phosphorus transport in animals with a normal supply of vitamin D was investigated. The intestinal P absorption was evaluated in rats using both the *in situ* duodenal loop technique and the determination of the overall gastrointestinal absorption under three conditions known to influence the production of $1,25\text{-(OH)}_2D_3$: (a) variation in dietary P, (b) thyroparathyroidectomy (TPTX) with or without administration of parathyroid hormone (PTH), and (c) treatment with disodium ethane-1-hydroxy-1,1-diphosphonate (EHDP). In all circumstances, changes in duodenal absorption paralleled the changes in the overall fractional absorption. Lowering dietary P stimulated P absorption. TPTX decreased P absorption. This effect was corrected either by the administration of PTH or by the administration of $1,25\text{-(OH)}_2D_3$. EHDP, when given at a dose known to inhibit $1,25\text{-(OH)}_2D_3$ formation, decreased the duodenal P absorption in both intact and TPTX animals. This effect was corrected by $1,25\text{-(OH)}_2D_3$. In the TPTX-EHDP-treated animals, the administration of PTH did not rectify the low duodenal P absorption. These results support the thesis that, in rats with normal vitamin D supply, variations in the endogenous production of $1,25\text{-(OH)}_2D_3$ change the rate of P absorption. However, these changes are in such magnitude that they are of relatively small importance when compared to the effect of variation in the dietary intake of P. These results also strongly suggest that the action of PTH on duodenal P transport is mediated by its effect on $1,25\text{-(OH)}_2D_3$ production, inasmuch as the effect of the hormone is abolished after blocking the renal 1-hydroxylation with EHDP.

0028 CYCLIC AMP-DEPENDENT AMINO ACID UPTAKE IN INTESTINE--THE IMPORTANCE OF β-ADRENERGIC AGONISTS. (Eng.) Kinzie, J. L.; Grimme, N. L.; Alpers, D. H. (Washington Univ. Sch. Medicine, St. Louis, MO 63110). *Biochem. Pharmacol.* 25(24):2727-2731; 1976.

Cyclic AMP (cAMP)-dependent stimulation of neutral and dibasic amino acid uptake by intestinal mucosa was investigated, using everted rat intestinal rings. β-Adrenergic receptor sites on the mucosal cell itself were implicated, since epinephrine and isoproterenol stimulated uptake *in vitro*, and this uptake was blocked by propranolol. Glucagon, vasopressin, and norepinephrine had no effect on tissue cAMP levels or on amino acid uptake, but cholera toxin given *in vivo* increased both parameters tested *in vitro*. Theophylline and isoproterenol caused an increase in cAMP levels in the villus tip cells, where these drugs also stimulated amino acid uptake. Neither drug increased cAMP in crypt cells. Thus, the cAMP-stimulated uptake of amino acids *in vitro* is a function of the villus tip cells. Moreover, when metabolic products, such as cAMP, are measured in whole intestinal mucosa, it cannot be assumed that the change is uniform throughout the tissue, but may involve only one type of cell on the intestinal villus.

0029 PROTEIN, DIPEPTIDE, AND AMINO ACID ABSORPTION IN THE YOUNG OF PROTEIN-DEPRIVED RATS. (Eng.) Zeman, F. J.; Fratzke, M. L. (Dept. Nutrition, Univ. California, Davis, CA 95616). *Pediatr. Res.* 11(9):972-977; 1977.

The quantitative effect of prenatal protein deficiency on protein, dipeptide, and amino acid transport was studied in Sprague-Dawley rats, and experiments were carried out to determine whether alterations in the absorption of these substances could be correlated with a decreased population of enterocytes or their reduced functional ability. Absorption was studied *in vivo* by infusing intestines of newborn and postnatal young of female rats (fed diets containing 4% or 24% casein during pregnancy) with 50 mM ^{14}C-labeled 1-aminocyclopentane-1-carboxylic acid (ACC), α-aminoisobutyric acid (AIB), glycyl-1-L-leucine (GL), or 8% ^{3}H-histidine-labeled casein in 5% glucose and physiologic saline. Casein absorption was significantly reduced per absorptive cell in prenatally protein-deprived (PPD) young at birth ($p<0.05$), but there were no differences at 8 days of age. AIB absorption and retention were decreased in PPD newborn young compared to controls, whether expressed as a total, on the basis of body weight, or per enterocyte. At 12 days, total retention and absorption were reduced in PPD young, but all other differences no longer existed. ACC absorption was reduced in PPD young, compared to controls, regardless of the means of expression. Retention of ACC per enterocyte was increased at birth compared to controls. These differences had disappeared by 8 days. GL retention was increased in PPD young compared to controls at birth, but not at 8 days. The data on casein absorption indicate that newborn PPD young are handicapped at some point in the processes of amino acid absorption and digestion and protein absorption. The high retention of dipeptide per enterocyte may be the consequence of a decreased ability of the enterocytes of PPD young to hydrolyze the dipeptide or may be the result of increased incorporation of these materials into mucosal protein. There is apparently a marked difference between the effects of intestinal absorption of prenatal protein deprivation and those of postnatal malnutrition. It is suggested that the competence of the enterocytes is reduced in newborn PPD young, whereas animals whose prenatal nutrition was normal begin life with a larger complement of fully differentiated absorptive cells and might therefore be capable of greater adaptation to the nutritional deficit.

0030 VITAMIN K$_2$ COLONIC AND ILEAL IN VIVO ABSORPTION: BILE, FATTY ACIDS, AND pH EFFECTS ON TRANSPORT. (Eng.) Hollander, D.; Rim, E.; Ruble, P. E., Jr. (Dept. Medicine, Wayne State Univ., Detroit, MI 48201). *Am. J. Physiol.* 233(2): E124-E129; 1977.

Colonic and ileal absorption of vitamin K$_2$ ([2-methyl-^{3}H]menaquinone-9) was investigated in the conscious rat, and the effects of the vitamin concentration, the thickness of the unstirred water layer, the concomitant presence of fatty acids, the intraluminal pH, and the intraluminal sodium taurocholate concentration on absorption were studied. When the absorption rate was plotted against the perfusate concentration, a linear relationship was found between these two parameters in the ileum and colon. The absorption rate of menaquinone by the ileum was increased as the bile salt concentration, degree of unsaturation of the added long-chain fatty acids, hydrogen ion concentration, and perfusate flow rates were increased. Colonic menaquinone absorption decreased as the bile salt concentration was increased. Menaquinone colonic absorption increased as the pH decreased, but no change was noted as the perfusion rate was increased. The present observations *in vivo*, coupled with prior observations *in vitro*, indicate that the absorption of menaquinone by the ileum and colon occurs by a passive diffusion process that is modified by variations in the perfusate bile salt concentration, the presence of unsaturated fatty acids, and the perfusate pH. The results indicate that the mammalian colon and terminal ileum can provide a constant source of vitamin K to aid hemostasis despite episodic lack of dietary vitamin K.

0031 SITE OF ACTION OF ACETYLCHOLINE IN REGULATING INTESTINAL EPITHELIAL ION TRANSPORT IN THE RAT [Abstract]. (Eng.) Browning, J. G.; Hardcastle, J.; Hardcastle, P. T.; Redfern, J. S. (Dept. Physiology, Sheffield Univ., Sheffield, England). *J. Physiol. (Lond.)* 270(1):78P-79P; 1977.

MOTILITY

0051 LONGITUDINAL FORCE AND STRESS OF RAT'S ESOPHAGUS: AGE-RELATED CHANGES. (Eng.) Zabinski, M. P.; Biancani, P. (Dept. Internal Medicine, Yale Univ., New Haven, CT 06510). *Am. J. Physiol.* 232(6):E580-E583; 1977.

The esophageal length, force, and stress characteristics were studied in rats, and the effect of age on these parameters was investigated. The longitudinal force-length relationship was studied *in vitro* in three age groups: 1, 3, and 12 months. The length of maximum force development (MFD) occurred at 1.4-1.5 times the *in vivo* length for all age groups. The active force developed at MFD increased markedly with age. The difference in the active forces in the 3-month and 12-month age groups is due to differences in cross section, because the active stress of the esophagus in the longitudinal direction was found to be approximately equal for the two age groups. The active stress in the 1-month-old rats was lower than in the 3-month-old rats, suggesting an increased contractility of the esophagus with age in this period of development.

0052 ESOPHAGEAL PERISTALTIC FORCE IN MAN: RESPONSE TO MECHANICAL AND PHARMACOLOGICAL ALTERATIONS. (Eng.) Schoen, H. J.; Morris, D. W.; Cohen, S. (Hosp. Univ. Pennsylvania, Philadelphia, PA 19104). *Am. J. Dig. Dis.* 22(7):589-597; 1977.

Studies were carried out in eight healthy subjects to quantify human esophageal peristaltic force, to determine the factors that alter this force, and to evaluate the relationship between force and intraluminal pressure. Force was measured using a mercury-in-Silastic strain gauge. Simultaneous pressures were obtained through constantly infused open-tipped catheters. On separate days, a sphere of either 6.0-, 9.0-, or 13.0-mm diameter was attached to the strain gauge, and measurements were obtained at three esophageal levels. Studies were done (a) with the subject at rest, (b) while performing a Valsalva maneuver, (c) during the administration of bethanechol (0.1 mg/kg, s.c.), and (d) after atropine (0.01 mg/kg, i.v.). Peristaltic force increased directly with sphere size but inversely with distance from the lower esophageal sphincter. Intraluminal pressure did not change significantly with sphere size or at different levels of the esophagus. A Valsalva maneuver increased force and pressure significantly only in the distal esophagus. Bethanechol had no significant effect on force at any esophageal level, but atropine decreased force at each esophageal level and with each sphere size. The distal esophageal response to a Valsalva maneuver was lost following atropine. Intraluminal pressure was a good index of peristaltic force, providing sphere size and esophageal level remained unaltered. These studies suggest that esophageal peristaltic force may be altered by bolus size, extrinsic maneuvers that alter intraluminal pressure (Valsalva maneuver), and certain pharmacological agents.

0053 CALCIUM DEPENDENCE OF NEUROMUSCULAR EVENTS IN ESOPHAGEAL SMOOTH MUSCLE OF THE OPOSSUM. (Eng.) de Carle, D. J.; Christensen, J.; Szabo, A. C.; Templeman, D. C.; McKinley, D. R. (Univ. Hosp., Iowa City, IA 52242). *Am. J. Physiol.* 232(6):E547-E552; 1977.

The relationship between extracellular calcium concentration and resting active tension and nerve-mediated events in the sphincteric or esophagogastric junctional region was examined. Intramural nerves in smooth muscle strips from opossum esophagus were stimulated electrically to cause contractions of longitudinal body muscle, off responses of transverse body muscle, and relaxations of sphincter muscle. Krebs solution was modified by calcium removal, by strontium substitution for calcium, by adding magnesium (2.4-22.4 mEq/l), and by adding nitroprusside (10^{-7}-10^{-5} M). Longitudinal muscle contractions were abolished by calcium removal and by excess magnesium; they were unaffected by nitroprusside; strontium could not replace calcium. Off responses were abolished by calcium removal and by excess magnesium; they were depressed by nitroprusside; strontium effectively replaced calcium. Resting active tension in sphincter strips was partly reduced by calcium removal and by excess magnesium; it was abolished by nitroprusside; strontium could not replace calcium. Relaxations in sphincter strips were unaffected by all experimental conditions. Longitudinal contractions, off responses, and resting active tension of the sphincter represent different kinds of calcium activation of muscle. The excitatory nerves (which are cholinergic) in longitudinal muscle are calcium dependent, whereas the nerves that produce off responses may not be. The nerves that relax the sphincter are not calcium dependent.

0054 THE INFLUENCE OF THE CALCIUM ANTAGONIST FENDILINE ON TONE AND MOTILITY OF THE GUINEA PIG GUT SMOOTH MUSCLE AND THE cAMP AND cGMP CONCENTRATIONS OF THE ISOLATED TERMINAL ILEUM.

(Eng.) Sprugel, W.; Mitznegg, P.; Heim, F. (Pharmakologischen Instituts der Universitat Erlangen-Nurnberg, 8520 Erlangen, W. Germany). *Arzneim. Forsch.* 27(3):571-574; 1977.

The effect of *N*-(2-benzhydryl-ethyl)-*N*-(1-phenylethyl)-amine hydrochloride (fendiline) on smooth muscle tone was studied in the guinea pig gastrointestinal tract, and the interactions between this drug and calcium, cyclic AMP, cyclic GMP, and theophylline in the terminal ileum were examined. Fendiline decreased the smooth muscle tone elevated by K^+-induced depolarization. This effect was antagonized by the addition of extra-Ca^{++}. The muscle relaxation was dose-dependent and amounted to 45-90% after 1-5 μg/ml fendiline. Proportionally to this effect, the tissue concentration in cyclic GMP was decreased whereas cyclic AMP remained unchanged. After 54 μg/ml theophylline, the cyclic AMP level in the terminal ileum was increased significantly, whereas cyclic GMP did not change. Theophylline had no influence on the relaxing effect of 1 μg/ml fendiline. By contrast, the increase in cyclic AMP after theophylline was prevented by fendiline. These findings are explained by the antagonistic effect of fendiline to Ca^{++}, which activates the guanylate cyclase and inhibits the adenylate cyclase. Fendiline seems to prevent the binding of theophylline to guinea pig ileal phosphodiesterase.

0055 SHORT CIRCUIT CURRENT AND TOTAL CONDUCTANCE MEASUREMENTS ON RAT ILEUM.

(Eng.) Emilio, M. G.; De Jesus, C. H. (Centro de Biologia, Instituto Gulbenkian de Ciencia, Oeiras, Portugal). *J. Physiol. (Lond.)* 270(1):209-222; 1977.

To determine the effects of different sugar molecules (D-glucose, 3-*O*-methyl-D-glucose, and 3-deoxy-3-fluor-D-glucose) on short circuit current and total conductance of the intestine, these measurements were made in preparations of rat terminal ileum, using either the intact tissue or the isolated epithelium. An increase in both short circuit current and total conductance was detected when these sugars were used. The Km and Vm values for the increase in short circuit current with glucose exhibited Michaelis-Menten kinetics were 2.8 mM and 69 $\mu A/cm^2$, resp. The values were 7.7 mM and 37 $\mu A/cm^2$, resp., with 3-*O*-methyl-D-glucose, and 47.6 mM and -61.7 $\mu A/cm^2$ with 2-deoxy-D-glucose. It was possible to determine a linear relationship between the two variables and to study the kinetics of the interaction of glucose and 3-*O*-methyl-D-glucose with the sodium sugar carrier by using increasing concentrations of these substances. The increases in short circuit current and total conductance were also verified in isolated epithelium. Phlorizin (5×10^{-6}-10^{-5} M), or the withdrawal of glucose reversed the increase in short circuit current, but the total conductance remained unchanged. Increasing concentrations of 2-deoxy-D-glucose added to the mucosal bathing medium caused a decrease in short circuit current without changing the total conductance, either in preparations of intact ileum or in isolated epithelium.

0056 MECHANICAL PROPERTIES OF TAENIA COLI SMOOTH MUSCLE IN SPONTANEOUS CONTRACTION.

(Eng.) Price, J. M.; Patitucci, P.; Fung, Y. C. (Coll. Medicine, Univ. South Florida, Tampa, FL 33612). *Am. J. Physiol.* 233(1):C47-C55; 1977.

To determine the dependence of mechanical properties on the length of the tenia coli smooth muscle, the following mechanical tests were carried out in spontaneously contracting guinea pig tenia coli: isometric step stretch, isotonic step loading, and length-tension. Passive stress-strain tests were also performed. Information on spontaneous contraction was more readily obtained in isometric tests. In length-tension tests, each isometric contraction was analyzed on a phase plane, which is a representation of muscle stress, $\sigma(t)$, versus the rate of change of stress, $\sigma(t)$. The curve in the phase plane provided parameters for describing spontaneous contraction as a function of muscle length, L. The maximum active stress in a cycle of spontaneous contraction, $S(L)_{max}$, and the maximum rate of increasing active stress, $[S(L)]_{max}$, where shown to depend on L in the same way. Both parameters attained a maximum value (upper bound) at the same muscle length, L_{max}. When L was less than L_{max}, the minimum stress in a spontaneous contraction, $\sigma(L)_{min}$ was negligible. If L was greater than L_{max}, $\sigma(L)_{min}$ increased nonlinearly and was equal to the passive stress in an epinephrine-relaxed muscle. The results show that the ratio of $[S(L)]_{max}$ to $S(L)_{max}$ is constant for a physiological range of muscle length. This suggests that the ratio of $[S(L)]_{max}$ to $S(L)_{max}$ may be used as an index of contractility for tenia coli.

0057 PATTERNS OF GASTRIC ELECTRICAL AND MOTOR ACTIVITY IN MINIATURE PIGS.

(Eng.) Roze, C.; Couturier, D.; Debray, C. (Hopital Bichat, 170 Bd Ney, 75877 Paris, Cedex 18, France). *Can. J. Physiol. Pharmacol.* 54(5):764-773; 1977.

Electrical and motor gastric patterns were recorded with chronically implanted electrodes and strain gauge force transducers in fasted and fed miniature Pitman Moore pigs to determine the usefulness of this model for physiological and pharmacological research. The patterns of gastric myoelectrical activity in pigs were generally similar to those observed in dogs, including regular cyclic potential variations in the distal two-thirds of the gastric wall and spike response activity following pacesetter potentials (PP), which was associated with muscle contraction. In fasting animals the frequency and propagation velocity of PP in the distal stomach (<11 cm from the pylorus) ranged from 3.78 ± 0.129 to 4.66 ± 0.130 cycles/min and 4.9 ± 0.18 to 7.8 ± 0.31 mm/sec, resp. There was a significant ($p<0.001$) level of variance in these parameters between different animals studied and between sessions for each animal. The following electrical and motor activity patterns were found to be peculiar to the miniature pigs studied: conduction velocity of the PP was increased only moderately in the antrum compared with a fourfold increase for dogs; tachygastria never occurred in pigs; a slight and progressive increase in PP frequency was observed in response to a standard meal and lasted for 2-4 hr; meal-induced contractions were of large amplitude and proceeded immediately at the maximal contracting force of the stomach; and the periodic reinforcement of spiking that is characterized in dogs by the migrating electrical complexes was not observed. The 40-min period following the administration of a test meal appeared especially suitable for pharmacological or physiological experiments in which inhibitory factors on the stomach are tested.

0058 MEAN TRANSIT TIME OF SOLID TEST MEALS IN GASTRIC EMPTYING.

(Eng.) Aeberhard, P.; Steudler, G.; Noelpp, U.; Rosler, H. (Inselspital, CH-3010 Bern, Switzerland). *Digestion* 15(5):361-372; 1977.

Gastric emptying of a technetium-labeled test meal was studied in nine healthy volunteers using a gamma-camera with on-line computer. Mean transit time (MTT) was determined by fitting the time-activity histogram to a gamma-variate, and the half-time of emptying ($T_{1/2}$) was calculated by exponential fitting of the down slope of the time-activity curve. MTT showed a smaller coefficient of variance than $T_{1/2}$. This result suggests that MTT may be a more suitable parameter for definition of normal values and for the separation of normal from pathological patterns of emptying.

0059 THE ROLE OF THE EXTRINSIC ANTRAL NERVES IN THE REGULATION OF GASTRIC EMPTYING.

(Eng.) Mroz, C. T.; Kelly, K. A. (Mayo Medical Sch., Rochester, MN). *Surg. Gynecol. Obstet.* 145(3):369-377; 1977.

The hypothesis that extrinsic antral nerves enhance gastric emptying of solids both by initiating and strengthening the bursts of powerful contractions that occur periodically during fasting and by stimulating antral peristalsis and trituration during feeding was tested. In six conscious dogs with chronically implanted gastric and duodenal electrodes, gastric emptying of 40 radiopaque plastic spheres (7 mm diameter, specific gravity 1.6) was assessed fluoroscopically during fasting and after the feeding of boiled beef liver (25 g of 1-cm cubes). Gastric emptying of 400 ml of 154 mM sodium chloride marked with ^{14}C-polyethylene glycol was also measured. The extrinsic antral nerves were then transected, and after recovery, the tests were repeated. Before antral denervation, gastric spheres were emptied predominantly during activity fronts--the 5- to 15-min bursts of action potentials and contractions that sweep aborally from the stomach to the colon every 2 hr during fasting. Feeding abolished activity fronts for about 8 hr, and, therefore, delayed gastric emptying of the spheres. After antral denervation, antral activity fronts were irregular, less frequent, and of shorter duration, and the spheres emptied slower both during fasting and after feeding. In contrast, the emptying of isotonic sodium chloride was unchanged. It is concluded that antral extrinsic nerves enhance gastric emptying of solid spheres but not of isotonic sodium chloride.

0060 PROLONGATION OF GASTRIC EMPTYING BY ORAL PROPANTHELINE.

(Eng.) Hurwitz, A.; Robinson, R. G.; Herrin, W. F. (Univ. Kansas Medical Center, Kansas City, KS 66103). *Clin. Pharmacol. Ther.* 22(2):206-210; 1977.

The effect of a frequently used p.o. dose of propantheline bromide (30 mg) on gastric emptying of a radioisotope-labeled test meal was studied. In a prospective, double-blind, randomized crossover design, 13 normal subjects received propantheline or placebo 90 min before taking a 113m-indium-labeled liquid test meal, the volume of which was adjusted to body weight. The disappearance of radioisotope from the area of the stomach was determined by external gamma counting. After placebo, the mean half-emptying time was 68 min, and after propantheline it was 135 min ($p<0.005$). Although salivary flow decreased and pulse rate increased, there were no visual disturbances. This study demonstrates that a single 30-mg dose of propantheline bromide doubles the mean gastric half-emptying time in man.

0061 MYOELECTRICAL AND MECHANICAL ACTIVITY OF STOMACH AND INTESTINE IN HYPOTHYROID DOGS.

(Eng.) Kowalewski, K.; Kolodej, A. (Surgical-Medical Res. Inst., Univ. Alberta, Edmonton, Alberta T6G 2N8, Canada). *Am. J. Dig. Dis.* 22(3):235-240; 1977.

Myoelectrical activity was studied in normothyroid and hypothyroid dogs in the resting state, following injection of pentagastrin (6 µg/kg, i.m.) or bethanechol chloride (50 µg/kg, i.m.), or after feeding. Hypothyroidism was produced by total thyroidectomy and chronic treatment with thiouracil. Electrodes were surgically implanted over the serosa of the stomach, duodenum, jejunum, and ileum and used for repeated recording of myoelectrical activity of gastrointestinal muscles. A strain gauge was implanted over the gastric antrum, and served to record mechanical activity of the stomach. Compared with controls, hypothyroid animals showed decreased frequency of electrical control activity of the stomach (22% decrease, $p<0.01$) and jejunum ($p<0.01$), decreased occurrence of electrical response activity (spike potentials) following stimulation, and decreased mechanical response to the same stimulants, i.e., pentagastrin, bethanechol chloride, and food. The abnormalities in the motor activity of the gastrointestinal muscles in clinical and experimental thyroid deficiency may be due to metabolic and functional changes in the muscle cells.

0062 STIMULATORY (H_1) AND INHIBITORY (H_2) HISTAMINE RECEPTORS IN GALLBLADDER MUSCLE. (Eng.) Waldman, D. B.; Zfass, A. M.; Makhlouf, G. M. (Medical Coll. Virginia, Richmond, VA 23298). *Gastroenterology* 72(5):932-936; 1977.

The nature of histamine receptors in guinea pig gallbladder muscle was examined using specific histamine-receptor agonists and antagonists. Metiamide (10^{-4}-10^{-3} M) augmented the contractile response to histamine, indicating that gallbladder muscle possessed stimulatory H_1 receptors and inhibitory H_2 receptors. The independent inhibitory character of H_2 receptors was confirmed by (a) induction of relaxation with histamine after H_1-receptor blockade and the suppression of this relaxation with metiamide, and (b) induction of relaxation with 4-methyl histamine, and the suppression of this relaxation with metiamide. Blockade of H_2 but not of H_1 receptors augmented the response to the octapeptide of cholecystokinin. The nature of this effect was such that the apparent affinity of the octapeptide for its own receptor was increased. The findings raised the possibility that, in their native unoccupied state, H_2 receptors may modify the response to hormonal agents.

SECRETION AND METABOLISM

Stomach

0079 GLYCOPROTEIN SYNTHESIS IN GASTRIC EPITHELIAL CELLS OF THE RAT. PROPERTIES OF MICROSOMAL GLYCOPROTEIN GLYCOSYLTRANSFERASES. (Eng.) Strous, G. J. A. M.; Kramer, M. F. (Dept. Histology Cell Biology, Univ. Utrecht, Nic. Beetsstraat 22, Utrecht, Netherlands). *Biochim. Biophys. Acta* 451(1):201-211; 1976.

The mechanism of the biosynthesis of the epithelial glycoproteins that line the inner surface of the mammalian stomach was investigated in tissue preparations from the Wistar rat. An assay method was devised for determining microsomal glycoprotein galactosyl- and fucosyltransferase in gastric scrapings, using both exogenous and endogenous glycoprotein. Subcellular fractionation of the homogenate yielded microsomal fractions that were high in the glycosyltransferases, with the probable location of fucosyltransferase on the rough endoplasmic reticulum and the galactosyltransferases on the Golgi apparatus. The amount of galactosyltransferase in the total cell homogenate was increased when studied after rats were starved for 48 hr and then permitted access to food for 3 hr (0.51 ± 0.034 nmol/min/μg DNA versus 0.65 ± 0.052 nmol/min/μg DNA, $p<0.01$). The endogenous acceptor molecule was identified as a glycoprotein.

0080 MOLECULAR FORMS OF GASTRIN IN THE ANTRAL MUCOSA. PLASMA AND GASTRIC JUICE DURING VAGAL STIMULATION OF ANESTHETIZED CATS. (Eng.) Unvas-Wallensten, K.; Rehfeld, J. F. (Karolinska Institutet, Stockholm, Sweden). *Acta Physiol. Scand.* 98(2):217-226; 1976.

Antral mucosa, blood, and gastric juice samples collected from anesthetized cats during electrical vagal stimulation were subjected to gel filtration to characterize the different molecular forms of gastrin. The gastrin concentration in the antral mucosa ranged from 2.82 to 3.60 μg/g mucosa, and the predominant gastrin form in antral mucosa was component III (gastrin-17), which accounted for about 94% of the total immunoreactivity. The antrum also contained 5% component II (gastrin-34) and 1% component I gastrin as well as trace amounts of component IV (gastrin-14). The gastrin concentration in the gastroduodenal vein (mainly draining the antrum) at 30-60 min after the start of vagal stimulation was as high as 12,400 pg/ml. Immediately after vagal stimulation, component III gastrin appeared in the gastric venous effluent followed within a few minutes by component IV gastrin. Component I or II gastrin was not detectable in plasma samples. It is suggested that component III gastrin is released from the antral mucosa and is then rapidly metabolized to component IV gastrin, possibly to a significant extent in the fundic region of the stomach. Gastrin levels of approximately 45,000 pg/ml were found in some gastric juice samples that contained large amounts of component III. Only very small amounts of immunoreactive degradation products were present in gastric juice, indicating that cat gastrin is relatively resistant to peptic degradation and acid hydrolysis.

0081 CHARACTERIZATION OF AN ADENYLATE CYCLASE SYSTEM SENSITIVE TO HISTAMINE H_2-RECEPTOR EXCITATION IN CELLS FROM DOG GASTRIC MUCOSA.

(Eng.) Scholes, P.; Cooper, A.; Jones, D.; Major, J.; Walters, M.; Wilde, C. (Imperial Chemical Industries Ltd., Pharmaceuticals Div., Mereside, Alderley Park, Macclesfield, Cheshire SK 10 4TG, England). *Agents Actions* 6(6):677-682; 1976.

The effect of histamine on the cyclic AMP level was investigated in canine gastric mucosal cells. Cyclic AMP in these cells was elevated by histamine and 4-methyl histamine, but 2-methyl histamine was only a weak agonist. The effects on cyclic AMP levels were inhibited competitively by metiamide and burimamide, which gave apparent K_B values of 3.5×10^{-7} M and 2.3×10^{-6} M, resp. These values are similar to those reported for other histamine H_2-receptor systems. The H_1-receptor antagonists, mepyramine and chlorpheniramine, had no inhibitory effect on the histamine-induced elevation of cyclic AMP; promethazine inhibited the system, but not by a competitive mechanism. It is concluded that the histamine-stimulated adenylate cyclase system is probably located in the parietal cell component.

0082 EFFECT OF ATROPINE AND METHIAMIDE ON VAGALLY INDUCED GASTRIC ACID SECRETION AND GASTRIN RELEASE IN ANESTHETIZED CATS.

(Eng.) Uvnas-Wallensten, K.; Andersson, H. (Karolinska Institutet, Stockholm, Sweden). *Acta Physiol. Scand.* 99(4):496-502; 1977.

The response of vagally-stimulated gastric acid secretion and gastrin release to atropine and methiamide was investigated in anesthetized cats. The vagal nerves, cut in the cervical region, were electrically stimulated (7 V, 2-5 msec, 2-10 Hz) for 1-3 hr to study gastric acid secretion or 5 or 10 min to study gastrin release. Atropine (0.1-0.3 mg/kg) or methiamide (4, 10, and 20 mg/kg) was administered 30-60 min after the beginning of electrical stimulation, and mean acid output was calculated before (last 15 min) and after (first two 15-min periods) the drug administration. To study gastrin release, atropine (0.1-2 mg/kg) or methiamide (20 mg/kg) were administered 15 min after the first and 10 min prior to the second electrical stimulation. Atropine reduced vagally stimulated gastric acid secretion approximately 40 and 30% of control values in the first and second 15-min periods following drug administration, resp. Methiamide reduced gastric acid secretion to about 30 and 10% of control values in the first two 15-min periods after drug administration. Gastrin release was not reduced by either drug. Possible explanations for the insensitivity of vagally induced gastrin release to atropine are discussed. It is suggested that the insensitivity of the neuroeffector junctions at the antral G cells to atropine and methiamide may be due to the presence of noncholinergic fibers stimulating the antral G cells or to nonmuscarinic cholinergic receptors.

0083 EFFECT OF HISTAMINE H_2 ANTAGONISM BY METIAMIDE ON THE RESPONSE OF THE CANINE GASTRIC MUCOSA TO ACID AND BILE SALT.

(Eng.) Gurll, N. J.; Zinner, M. J.; Callahan, W. (Walter Reed Army Inst. Res., Washington, DC). *Gastroenterology* 73(2):255-259; 1977.

To clarify the effect of histamine H_2-receptor antagonists on gastric mucosa damaged by acid or acid plus sodium taurocholate, the effects of i.v. metiamide infusion on three characteristics of the gastric mucosa (the ionic fluxes of Na^+ and H^+, transmural potential difference [PD], and protein loss into the gastric lumen) were determined in five awake mongrel dogs. Denervated Heidenhain (fundic) pouches were prepared in the dogs, and antrectomy was performed followed by gastroduodenostomy. Experiments began 3 weeks later, and each dog was tested once a week for 2 months. The pouch lumen was perfused with 70 ml of either 80 mM HCl plus 80 mM NaCl (ATS) or ATS plus 20 mM sodium taurocholate (BS) for 3 hr at 37 C. Metiamide or 0.9% NaCl was infused i.v. at 10 µmol/kg/hr, beginning 30 min prior to perfusion of the pouch. Each dog was tested twice with each of the four possible combinations of agents. Exposure to ATS produced increases in the Na^+, Cl^-, and K^+ outputs, as well as in the luminal volume. During exposure to ATS, metiamide increased the mean H^+ clearance rate from -0.5 ± 0.5 to -1.9 ± 0.5 ml/30 min ($p<0.05$), but did not affect the PD, ion fluxes, or luminal volume. Exposure to BS increased the net Na^+ flux threefold and the K^+ gain by fourfold, in addition to increasing the volume and H^+ clearance rate. Metiamide infusion did not significantly alter the total mean H^+ clearance rate or ion fluxes during exposure to BS. The mean hourly net H^+ loss was significantly increased ($p<0.05$) by metiamide during the first 2 hr of exposure to BS even though H^+ concentration and PD were not affected. In addition, Cl^- gain was much lower than control values (BS alone) during the second and third hours, suggesting that acid secretion was reduced; this finding may also explain the increase in H^+ loss.

Metiamide infusion reduced the protein loss during exposure to BS in three of five dogs from >50 mg/3 hr to <20 mg/3 hr. These observations suggest that histamine may mediate gastric mucosal damage, particularly that resulting from exposure to BS.

0084 METIAMIDE AND STIMULATED ACID SECRETION FROM THE ISOLATED NON-DISTENDED AND DISTENDED MOUSE STOMACH.

(Eng.) Wan, B. Y. C. (Univ. Coll. London, Gower St., London WC1E 6BT, England). *J. Physiol. (Lond.)* 266(2):327-346; 1977.

The action of metiamide on the acid secretory response to various gastric stimuli in the perfused, isolated, distended, or nondistended mouse stomach was investigated. The distended stomach gave a marked and dose-related acid secretory response to histamine (HA, 10^{-6}-10^{-3} M), pentagastrin (PG, 10^{-8}-10^{-5} M), acetylcholine (5 x 10^{-5}-10^{-5} M), eserine (10^{-5}-10^{-3} M), or dibutyryl cyclic AMP (dbcAMP, 5 x 10^{-5}-10^{-3} M). In the nondistended stomach, dbcAMP regularly stimulated acid secretion in a dose-dependent manner; HA, PG, or acetylcholine did not always stimulate acid secretion. HA or PG, but not acetylcholine, always caused significant stimulation of acid secretion from the nondistended stomach in the presence of a phosphodiesterase inhibitor such as caffeine, theophylline, or the I.C.I. compound, 63197. At 10^{-4} M, these phosphodiesterase inhibitors markedly potentiated the stimulatory effect of HA or PG on acid secretion, and the order of effectiveness was 63197>theophylline>caffeine. 63197 Potentiated HA- or PG-stimulated acid secretion in the distended stomach markedly. Metiamide (5 x 10^{-5}-10^{-4} M) did not antagonize stimulation of acid secretion by dbcAMP in the nondistended or distended stomach. In the distended stomach, metiamide (5 x 10^{-5} M) significantly inhibited HA-stimulated acid secretion with a linear and parallel displacement of the HA dose-response curve to the right. Although at this concentration metiamide did not depress the maximal acid secretory response to HA, it markedly reduced the maximal acid secretory response attainable with PG. In the distended stomach, metiamide (5 x 10^{-5} M) did not inhibit acetylcholine-induced acid secretion significantly. Atropine (5 x 10^{-6} M) abolished the stimulatory effect of acetylcholine; it also inhibited PG-stimulated acid secretion, but it had little effect on acid secretion induced by HA. The results indicate that metiamide inhibits HA-induced acid secretion by competitive antagonism of the HA H_2-receptor, but its inhibitory effect on PG-induced acid secretion seems to be of a noncompetitive nature. The failure of metiamide to inhibit acid secretion induced by dbcAMP suggests that cAMP might regulate gastric acid secretion at a site beyond the H_2-receptor activation. The present results support the hypothesis that cAMP may be involved in HA-induced acid secretion in the isolated mouse stomach.

0085 EFFECT OF HISTAMINE ON TECHNETIUM-99m EXCRETION BY GASTRIC MUCOSA.

(Eng.) Wine, C. R.; Nahrwold, D. L.; Rose, R. C.; Miller, K. L. (Milton S. Hershey Medical Center, Hershey, PA 17033). *Surgery* 80(5):591-594; 1976.

The effects of histamine on ^{99m}technetium (Tc) pertechnetate (TcP) excretion by denervated antral and oxyntic gland mucosa were studied in four dogs prepared with a separated denervated antral pouch and a Heidenhain pouch and fasted for 18 hr prior to secretory studies. After an infusion of 0.15 M sodium chloride for two 15-min periods, histamine dihydrochloride (0.01, 0.02, or 0.16 mg/kg/hr) was constantly infused for twelve 15-min periods. After histamine had been infused for four 15-min periods, the dogs received a single rapid i.v. injection of TcP (0.9-1.6 mCi). All histamine doses caused a significant increase in Heidenhain pouch acid output that plateaued within 1 hr after the start of histamine infusion. Acid output was not affected by the TcP injection. Heidenhain pouch TcP output increased with increasing histamine doses. Peak TcP output (about 13 μCi/15 min) occurred at 30 min after a 0.16 mg/kg/hr histamine treatment and gradually declined thereafter. Peak TcP output (about 7 μCi/15 min) with a 0.02 mg/kg/hr histamine dose also occurred at 30 min after the start of histamine infusion, but the output remained at about the same level thereafter. With a histamine dose of 0.01 mg/kg/hr, there was a gradual increase in TcP output that reached about 6 μCi/15 after 2 hr of histamine infusion. When the mean total 2-hr TcP output was plotted against the mean 2-hr volume or acid output of gastric juice from Heidenhain pouches, a linear relationship was found in each case. Antral pouch secretion studies revealed no significant differences in pH, antral secretion volume, or antral pouch TcP output at different histamine doses. The maximum mean 2-hr TcP output from antral pouches (7.9 ± 0.9 μCi/2 hr) obtained with the highest histamine dose was less than one-third of the mean 2-hr output from Heidenhain pouches (26.6 μCi) obtained with the lowest histamine dose. The results suggest the possibility that TcP scanning accuracy in Meckel's diverticulum might be improved by the administration of histamine prior to TcP injection.

0086 EFFECT OF CALCITONIN ON GASTRIC SECRETION.

(Eng.) Yonaga, T.; Nakamura, K.; Matsuura, K. (Teikyo Univ. Sch. Medicine, Kaga 2-11-1, Itabashi-ku, Tokyo 173, Japan). *Proc. Jpn. Acad.* 52(9):532-535; 1976.

The mechanism of action of calcitonin (CT) on gastric secretion in rats with chronic gastric fistulas was investigated. The relation between CT action and serum calcium level was also studied in rats given an infusion of histamine (1 mg/hr) and calcium gluconate (2.5 mg/hr). Volume and acid and pepsin concentrations were measured in samples of gastric secretion collected every 30 min from rats injected s.c. with synthetic salmon CT (1 or 5 IU) dissolved in 1% acetic acid. Prior to the CT injection, rats had received saline alone (1.6 ml/hr infused through tail vein), saline infusions containing a stimulant of gastric secretion (histamine, 1 mg/hr; tetragastrin, 0.8 μg/hr; or bethanechol chloride, 20 μg/hr), or 2-deoxy-D-glucose (20 mg/rat), which is thought to stimulate the vagus nerve. Results revealed that CT completely inhibited stimulated and nonstimulated gastric secretion, although the degree of inhibition varied under different conditions. Gastric acid and pepsin secretions stimulated with histamine and calcium gluconate infusions were also inhibited by s.c. CT administration, indicating that the effect of CT on gastric secretion is independent of serum calcium levels.

0087 RELATIONSHIP OF THE GASTRIN RESPONSE TO THE AMOUNT OF FOOD INGESTED IN NORMAL SUBJECTS. (Eng.) Woussen-Colle, M. C.; Willems, G.; De Graef, J. (Hospital Saint-Pierre, Brussels, Belgium). *Digestion* 15(4):322-328; 1977.

The effect of the quantity of food ingested on the gastrin response was studied in eight normal subjects who received three different amounts of the same meal. The subjects received a meal that included 150 g of steak on one occasion, and on two other occasions one-half or twice this amount, resp. The peak gastrin response was similar for the three meals, but the integrated gastrin response was larger with the largest meals. A comparison of the response to the two largest meals indicated that in a given subject, the gastrin response is similar when tested on different occasions. A good correlation was found between individual fasting concentrations of gastrin and peak gastrin levels after feeding but not between basal gastrin and the integrated gastrin response. This finding could indicate that in normal subjects, the first two parameters are primarily related to the same control mechanisms (possibly the G cell mass), while the integrated gastrin response reflects the effectiveness of the feedback mechanisms controlling gastrin release.

0088 RESERPINE, CATECHOLAMINES AND VAGOTOMY IN THE RAT GASTRIC MUCOSA. AN ELECTRON MICROSCOPIC STUDY. (Eng.) Nyhus, L. M.; Kalahanis, N. G.; Das Gupta, T. K. (Abraham Lincoln Sch. Medicine, Chicago, IL). *Chir. Gastroenterol.* 10(4): 359-365; 1976.

The effects of reserpine on the enterochromaffin-like (ECL) cells of the rat fundic mucosa were examined. Fundic mucosa from control and reserpine (2.5 mg/kg x 2 days, i.p.)-treated animals was examined ultrastructurally. Reserpine caused an increase in the synthesis and release of ECL cell catecholamines. The increased local release of catecholamines may account for the ulcerogenic properties of reserpine. Previous studies have shown that vagotomy depletes the ECL cells of their granular content with no simultaneous increase in its synthesis; this effect may be one of the mechanisms whereby vagotomy prevents ulcer formation in reserpine-treated rats.

0089 EFFECT OF LYSINE-ACETYLSALICYLATE ON SERUM GASTRIN LEVELS. (Eng.) Estler, C. J.; Mitznegg, P.; Domschke, W.; Demling, L. (Dept. Pharmacology, Univ. Erlangen-Nurnberg, Universitatssr. 22, D-8520 Erlangen, W. Germany). *Acta Hepatogastroenterol.* 24(1):52-54; 1977.

The effect of lysine-acetylsalicylate (LAS) on serum gastrin levels was investigated in mice. Intragastrically administered LAS did not alter serum gastrin values, while a very high dose of LAS (450 μg/g) caused a short-lived, significant increase in serum gastrin (74.3 ± 17.1 versus 36.9 ± 7.6 pg/ml in controls, $p \leq 0.05$) when administered i.v. These results are consistent with the view that salicylates do not owe their potential ulcerogenic properties to stimulation of the gastrin-gastric secretion mechanism.

0090 PARIETAL CELLS OF THE STOMACH TRAP SALICYLATES DURING ABSORPTION. (Eng.) Brune, K.; Schweitzer, A.; Eckert, H. (Biocenter, Klingelbergstrasse 70, CH-4056, Basel, Switzerland). *Biochem. Pharmacol.* 26(18):1735-1740; 1977.

Autoradiographic methods were used to study the uptake of salicylates by the parietal cells in the stomach of rats. Whole-body autoradiographs taken 45 min after the administration of the ^{14}C-salicylic acid (10 μCi) showed activity in the kidneys and stomach wall but not in the stomach lumen or gut. Additional studies of thin slices of the stomach wall removed 1, 5, and 15 min after ^{3}H-salicylic acid administration indicated very rapid diffusion of the drug across the gastric wall in the glandular stomach. A method was devised for the rapid fixation of both the tissue and drug for autoradiography (immediate deep freezing of stomach wall in liquid propane, cutting in a cryostat at -25 C, mounting on emulsion and exposure at the same temperature). High drug concentrations were observed throughout the glandular stomach, but particularly in the parietal cells within 1 min of drug administration, indicating selective trapping of salicylate molecules by parietal cells. It is hypothesized that decay of the parietal cells is initiated by the salicylate immediately, and ulcers may be the ultimate outcome of this process. Results support the assumption that functioning parietal cells are essential for the development of ulcers due to salicylate medication, which would explain why achlorhydric patients rarely experience gastric side-effects from aspirin.

0091 THE EFFECT OF SEROTONIN ON PEPSIN INHIBITION BY DUODENAL FAT. (Eng.) Wazna, M. F.; Stein, T.; Wise, L. (Long Island Jewish-Hillside Medical Center, New Hyde Park, NY 11040). *Ann. Surg.* 186(2):130-135; 1977.

The role of serotonin in pepsin secretion was studied in dogs. Twelve female mongrel dogs were prepared with a Heidenhain pouch and gastric and duodenal cannulae. The purpose of the gastric cannulae was to divert stomach acid from the duodenum to prevent inhibition of gastric secretion during the experiment. Pretreatment with reserpine (0.1 mg/kg, i.m.)

abolished the stimulatory effect of histamine (0.04 mg/kg/hr) on pepsin secretion, while pretreatment by 1-methyl-d-lysergic acid butanolamide (2 mg/hr, i.v.) increased the pepsin inhibition resulting from the intraduodenal infusion of corn oil emulsion. 5-Hydroxytryptophan (20 mg/kg, i.v.) injected simultaneously with the intraduodenal corn oil caused marked increase in pepsin secretion. Since these effects were observed in the denervated Heidenhain pouch, it is suggested that serotonin acts directly as a hormone on gastric chief cells.

Pancreas

0107 PANCREATIC ACINAR CELLS: LOCALIZATION OF ACETYLCHOLINE RECEPTORS AND THE IMPORTANCE OF CHLORIDE AND CALCIUM FOR ACETYLCHOLINE-EVOKED DEPOLARIZATION. (Eng.) Iwatsuki, N.; Petersen, O. H. (Dept. Physiology, Univ. Dundee, Dundee DD1 4HN, Scotland). *J. Physiol. (Lond.)* 269(3):723-733; 1977.

Acetylcholine (ACh) receptors were localized in pancreatic acinar cells, and the importance of chloride and calcium for ACh-evoked depolarization was studied. Intracellular microelectrode recordings of acinar cell membrane potential and resistance were made from the mouse pancreas superfused *in vitro*. The acinar cells were stimulated by microiontophoretic ACh application from an extracellular AChCl-filled microelectrode. Passing short-lasting ejecting current pulses through the AChCl-electrode caused acinar cell depolarization when the electrode was in an extracellular position not far (<50 μm) from an acinus impaled by a KCl microelectrode. After the insertion of the AChCl electrode into a neighboring acinar cell, electrically coupled to the acinar cell already impaled by the KCl-electrode, ejecting ACh current pulses only affected the membrane potential in a direct electrical manner, whereas there was no sign of an effect of ACh on the membrane potential. Replacing extracellular chloride by sulfate caused a marked increase in the amplitude of the ACh-evoked depolarization. If the membrane potential was recorded with a KCl electrode, ACh continued to evoke very large depolarizations even after more than 1 hr exposure to Cl-free solution. If the membrane potential was recorded with a K-citrate electrode, the effect of Cl-removal was only transient. Removal of Na^+ during exposure to Cl-free solution reduced the amplitude of the ACh-evoked depolarization. Readmission of Cl after more than 1 hr of Cl deprivation caused an immediate reversal of the ACh effect into a hyperpolarization. Removal of extracellular Ca^{2+} caused a marked reduction in the amplitude of small depolarizations evoked by just suprathreshold doses of ACh, whereas there was very little effect on larger depolarizations evoked by maximal or supramaximal ACh ejections. The effect of Ca removal was fully reversible. The addition of Mn after Ca-deprivation was as efficient as Ca in restoring normal electrophysiological responses to small doses of ACh. The acinar cell membrane seems only to be responsive to ACh added to the extracellular side, and ACh probably causes an increase in membrane Cl permeability in addition to the previously described effects on Na and K permeability. Ca may be important in determining ACh receptor sensitivity.

0108 PANCREATIC ACINAR CELLS: THE ACETYLCHOLINE EQUILIBRIUM POTENTIAL AND ITS IONIC DEPENDENCY. (Eng.) Iwatsuki, N.; Petersen, O. H. (Dept. Physiology, Univ. Dundee, Dundee DD1 4HN, Scotland). *J. Physiol. (Lond.)* 269(3):735-751; 1977.

To gain insight into the ionic permeabilities of the pathways opened up by acetylcholine (ACh) in the pancreatic acinar cell membrane, the ACh equilibrium potential (E_{ACh}) was determined, and the effects of changes in K, Na, and Cl concentrations were investigated. Two glass microelectrodes were inserted into neighboring cells from rat or mouse pancreatic segments, superfused *in vitro*. The tip of a third glass microelectrode, filled with 2 M AChCl, was placed just outside the acinus. Membrane potential and resistance, and changes in these parameters in response to short pulses of ACh stimulation, were recorded. The resting current-voltage relationship, obtained by injecting 100 msec depolarizing or hyperpolarizing current pulses through one of the intracellular microelectrodes and recording the membrane potential with the other intracellular electrode, was linear within the range -5 to -60 mV. When the acinar cell membrane was hyperpolarized, the amplitude of ACh-evoked depolarization was increased, while ACh-evoked depolarization was reduced when the membrane potential was reduced by depolarizing current, and finally changed into a hyperpolarization at very low membrane potentials. In each acinus investigated (rat and mouse), there was a linear relationship between amplitude of ACh-evoked potential change (ΔV) and resting membrane potential. During superfusion with control solution, the value of the membrane potential at which ACh did not evoke a potential change was about -15 mV in the mouse and about -20 mV in the rat. During superfusion with a chloride-free sulphate-containing solution (steady state), a linear relationship between ΔV and resting membrane potential was again found, but E_{ACh} (mouse) was about +10 mV. Replacing extracellular chloride by sulfate caused an immediate change in E_{ACh} in the positive direction. Readmission of chloride, after a long period of chloride ion deprivation, caused an immediate sharp change in E_{ACh} in the negative direction. Replacing extracellular sodium by Tris caused an immediate transient negative change in E_{ACh}. In contrast, removing extracellular calcium changed E_{ACh} in a positive direction. Augmenting extracellular potassium concentration to 40 mM caused a change in E_{ACh} in the positive direction. At a membrane potential (V) equal to E_{ACh}, the sum of ionic currents evoked by the action of ACh is zero. ACh increased membrane Na, K, and Cl permeability. The approximate relative ion permeabilities of the pathways opened up by ACh are $P_{Na}/P_K=2.5$ and $P_{Cl}/P_K=5$. At $V=E_{ACh}$, the approximate relative sizes of the ACh-evoked currents are $I_{Na}/I_K=2.6$ and $I_{Cl}/I_K=1.6$. ACh, therefore, causes influx of Na and Cl and a small efflux of K.

0109 PARALLEL SECRETION OF DIGESTIVE ENZYMES BY THE IN VITRO RABBIT PANCREAS. (Eng.) Steer, M. L.; Glazer, G. (Beth Israel Hosp., Boston, MA 02215). *Am. J. Physiol.* 231(6):1860-1865; 1976.

The total output of proteins and the secretion of the enzymes, α-amylase, trypsinogen, and chymotrypsinogen by the rabbit pancreas stimulated *in vitro* by methacholine, cholecystokinin-pancreozymin (CCK-PZ), or Sincalide (C-terminal octapeptide of CCK-PZ) was studied. The entire pancreas with an attached loop of duodenum and segment of colon was excised *en bloc* from New Zealand white rabbits and mounted in an incubation chamber. Pancreatic juice samples were collected for 1-hr periods prior to and after addition of the stimulants to the incubation medium. The final concentration of methacholine added was 0.8 mg/100 ml, that of CCK-PZ was 4 Ivy dog U/100 ml, and that of Sincalide was 12 Ivy dog U/100 ml. The protein concentration was significantly increased ($p<0.01$ and $p<0.005$) in all juice samples collected after the addition of stimulants. When the ratio of each enzyme to the others for each animal and for each collection period was measured, only paralleled discharge of the three enzymes was observed. The results are consistent with the mass-transport theory of enzyme synthesis and secretion by the exocrine pancreas.

0110 EFFECT OF GLUCAGON ON THE SECRETORY PROCESS IN THE RAT EXOCRINE PANCREAS. (Eng.)

Adler, G. (Dept. Cell Biology and Cell Pathology, Philipps-Univ. Marburg, Robert-Koch-Str. 6, D-3550 Marburg, W. Germany). *Cell Tissue Res.* 182(2): 193-204; 1977.

The effect of glucagon on the enzymes, ultrastructure, and secretion of the pancreas was studied in rats. Glucagon (10-80 μg/hr) was infused i.v. into conscious rats for up to 24 hr. The effect on the secretory process was studied *in vitro* using isolated pancreatic lobules. A pronounced inhibition of the rate of protein synthesis and discharge of stored and newly synthesized proteins, combined with increased enzyme content, were observed after 30 min of infusion. At a glucagon infusion of 50 μg/hr, amylase, lipase, and chymotrypsin levels increased approximately 30% over the control levels. This effect was absent after longer infusion periods of up to 6 hr. After 12- to 24-hr infusions, a marked degranulation and decrease in enzyme content was observed. While the rate of protein synthesis was not significantly enhanced, both the basal and stimulated discharge of enzymes from the pancreas were increased. The results suggest a biphasic response of the pancreas to prolonged glucagon infusion.

0111 Ca^{++} FLUXES IN ISOLATED CELLS OF RAT PANCREAS. EFFECT OF SECRETAGOGUES AND DIFFERENT Ca^{++} CONCENTRATIONS. (Eng.)

Kondo, S.; Schulz, I. (Max-Planck-Institut fur Biophysik, 6 Frankfurt [Main], W. Germany). *J. Membr. Biol.* 29 (1/2):185-203; 1976.

The effects of secretagogues and of different calcium concentrations on ^{45}Ca influx and efflux were studied in isolated rat pancreatic cells to characterize the mechanism of Ca^{2+} transport. The secretagogues pancreozymin, carbamylcholine, gastrin I, the octapeptide of pancreozymin, and cerulein, as well as the Ca^{2+}-ionophore A 23187, stimulated ^{45}Ca efflux from isolated cells. The nonsecretagogic hormones isoproterenol, secretin, as well as dibutyryl cyclic AMP and dibutyryl cyclic guanosine 3',5'-monophosphate, had no effect on ^{45}Ca efflux. Atropine blocked the stimulatory effect of carbamylcholine on ^{45}Ca efflux completely, but not that of pancreozymin. A graphical analysis of the Ca^{2+} efflux curves revealed at least three phases: a first phase, probably derived from Ca^{2+} bound to the plasma membrane; a second phase, possibly representing Ca^{2+} efflux from cytosol of the cells; and a third phase, probably from mitochondria or other cellular particles. The Ca^{2+} efflux of all phases was stimulated by pancreozymin and carbamylcholine. Ca^{2+} efflux was not significantly affected by the presence or absence of Ca^{2+} in the incubation medium. Metabolic inhibitors of ATP production, Antimycin A and dinitrophenol, which inhibit Ca^{2+} uptake into mitochondria, stimulated Ca^{2+} efflux from the isolated cells, but inhibited the slow phase of Ca^{2+} influx, indicating the role of mitochondria as an intercellular Ca^{2+} compartment. Measurements of the $^{45}Ca^{2+}$ influx at different Ca^{2+} concentrations in the medium revealed saturation type kinetics, which are compatible with a carrier or channel model. The hormones mentioned above stimulated the rate of Ca^{2+} translocation. The data suggest that secretagogues of pancreatic enzyme secretion act by increasing the rate of Ca^{2+} transport, most likely at the level of the cell membrane, and that Ca^{2+} exchange diffusion does not contribute to the $^{45}Ca^{2+}$ fluxes.

0112 STIMULUS-SECRETION COUPLING IN PANCREATIC ACINAR CELLS: INFLUENCES OF EXTERNAL SODIUM AND CALCIUM ON RESPONSES TO CHOLECYSTOKININ-PANCREOZYMIN AND IONOPHORE A23187. (Eng.)

Kanno, T.; Saito, A.; Sato, Y. (Faculty Veterinary Medicine, Hokkaido Univ., Sapporo, 060, Japan). *J. Physiol. (Lond.)* 270(1):9-28; 1977.

The roles of sodium and calcium ions in stimulus secretion coupling were analyzed in the isolated and perfused rat pancreas. Partial replacement of NaCl with LiCl produced a diminution in both amylase output and pancreatic juice flow induced by cholecystokinin-pancreozymin (CCK-PZ, 5 mU/ml), and almost normal responses were usually regained immediately after the reintroduction of a standard concentration of NaCl. Nearly total replacement of NaCl with LiCl caused an almost complete inhibition of the responses, although 25 mM $NaHCO_3$ and 1 mM NaH_2PO_4 were still present, and only partial recovery was obtained after the reintroduction of a standard concentration of NaCl. A quantitative relation was found between the amount of amylase released by CCK-PZ and the $[Na^+]_0$ over the range 26-157 mM in the presence of 2.5 mM Ca. A similar relationship was also observed when $[Ca^{2+}]_0$ was decreased to 1.0 mM, but the responses were reduced to about one-half of those observed with 2.5 mM Ca. The cellular mechanism of CCK-PZ-induced amylase output may involve the dominant activity of a complex composed of a carrier molecule bearing one Ca and four Na molecules, if there is no interaction between Na^+ and Li^+. A quantitative relation was also found between the amount of pancreatic juice flow stimulated by CCK-PZ and $[Na^+]_0$ over the range 26-157 mM, in the presence of 1.0 or 2.5 mM Ca. A similar quantitative relationship was found between the amount of amylase released by Ca ionophore A23187 and $[Na^+]_0$ in the presence of 2.5 or 5.0 mM Ca. This may also involve the dominant activity of a complex composed of a carrier molecule bearing one Ca and four Na molecules, if there is no interaction between Na^+ and Li^+.

0113 THE EFFECT OF SOMATOSTATIN ON EXOCRINE PANCREAS SECRETION IN THE DOG STIMULATED BY PANCREOZYMIN-SECRETIN, OR BY A TEST MEAL.

(Ger.) Kayasseh, L.; Stalder, G. A.; Gyr, K.; Rittmann, W. W.; Girard, J. (Medizinische Universitatspoliklinik, Hebelstrasse 1, CH-4056 Basel, Switzerland). *Schweiz. Med. Wochenschr.* 107(15):541-542; 1977.

The effect of somatostatin (SST) on the exocrine pancreas of dogs with pancreatic and gastric fistulae was investigated during stimulation by pancreozymin-secretin or by a test meal. Chronic pancreatic and gastric fistulae were made following ligation of the minor pancreatic duct. The exocrine pancreas was infused with 2 IU of secretin-pancreozymin for 150-180 min, and SST was first given as a bolus injection (3.5 μg/kg) followed by infusion (3.5 μg/kg/hr). In another experiment, the pancreas was stimulated by means of an intragastrically administered Lundh test meal (5 ml/kg). SST caused a significant inhibition of stimulated enzyme secretion of the exocrine pancreas; protein secretion into the pancreatic juice was reduced by 54% (273.7 ± 57.2 to 125.8 ± 4 mg/hr) and amylase by 57.7% (42,115.9 ± 8,928.8 to 17,817 ± 5,098 U/hr). However, bicarbonate secretion and volume did not change significantly. The bicarbonate concentration was reduced by 8.1% (133.8 ± 1.7 U/hr to 123 ± 3.9 U/hr). The bilirubin content of the duodenal juice also decreased significantly (by 88%) during SST treatment (from 32 to 3.8 mg%). Similarly in the Lundh test meal trial, SST caused a 71% decrease in trypsin concentration (23 ± 3.3 to 6.7 ± μEqH^+/ml/min) and a 57.2% decrease in amylase level (208.5 ± 27.3 to 89.2 ± 18.4 U/ml). The total volume of duodenal juice was reduced by 51.2% (213 ± 29.6 to 104 ± 36.5 ml/hr).

0114 INFLUENCE OF SECRETIN ON CAERULEIN STIMULATED PANCREATIC SECRETION OF THE RAT.

(Eng.) Linari, G.; Linari, M. B. (Inst. Medical Pharmacology I, Univ. Rome, 0185 Rome, Italy). *Pharmacol. Res. Commun.* 9(7):633-641; 1977.

The pancreatic dose-response relationship to graded doses of cerulein was studied in female Wistar rats under acute fistula conditions. Cerulein (3.75-101.25 ng/kg/min, i.v.) was infused over a continuous secretin background (6 U/kg/hr). In comparison with rats that did not receive secretin, the flow of juice was significantly ($p<0.01$) increased in response to all doses of the peptide, but only the rate of 101.25 ng/kg/min produced a significant increase of amylase output. A good correlation between flow and enzyme secretion was seen. Amylase concentrations were about 30% lower than in animals not infused with secretin. The secretin background determined an increase of the calculated maximal response of amylase secretion to cerulein and a decrease of the ED_{50} value of the peptide. These studies demonstrate that the kinetics of the pancreatic response to cerulein are modified by a secretin background.

0115 AMINO ACID TRANSPORT IN THE RAT EXOCRINE PANCREAS. II. INHIBITION BY LANTHANUM AND TETRACAINE.

(Eng.) Bieger, W.; Peter, S.; Volkl, A.; Kern, H. F. (Dept. Anatomy, Univ. Heidelberg, Heidelberg, W. Germany). *Cell Tissue Res.* 180(1):45-62; 1977.

The effect of increasing concentrations of lanthanum and tetracaine on the accumulation of labeled neutral amino acids in the free intracellular pool of isolated rat pancreatic lobules was studied *in vitro*. The two calcium antagonistic agents caused severe disturbances in the secretory process of the exocrine pancreas, including inhibition of the rate of protein synthesis and exocytosis. The former effect resulted mainly from the inhibition of amino acid transport. Lanthanum (up to 1 mM) inhibited the transport of different species of amino acids in an unspecific way, whereas tetracaine interfered specifically with the Na^+-dependent transport system for neutral amino acids (^{14}C-α-aminoisobutyric acid). Na^+-independent transport of neutral amino acids (^3H-leucine) was not affected. Transport inhibition was correlated to the activity of the Na^+,K^+-ATPase system, which was measured in isolated plasma membrane fractions. At higher concentrations (5-10 mM), some uptake of lanthanum into the cells by limited endocytosis was observed. At lower concentrations, lanthanum seemed to bind exclusively to certain components of the plasma membrane, mainly at the lateral and basal cell surface. Even at 5-10 mM, no binding to the apical surface occurred. Similarly, lanthanum was not bound to the limiting membrane of isolated zymogen granules, but the mitochondria in the same fraction showed considerable binding affinity. The action of lanthanum and tetracaine on membrane carrier systems did not affect the interior organization of the plasma membrane. Particle density and distribution in freeze-fracture replicas as well as the submembrane microfilamentous-microtubular system and the junctional elements remained unaffected.

0116 EVIDENCES FOR DUODENOPANCREATIC REFLEXES AND ANTI-CCK FACTOR WITH LIDOCAINE INFUSED INTRAVENOUSLY AND SPRAYED TOPICALLY ON PANCREATIC PAPILLA IN NONALCOHOLIC AND ALCOHOL-FED DOGS.

(Eng.) Tiscornia, O. M.; Sarles, H.; Voirol, M.; Levesque, D.; Dzieniszewski, J.; Palasciano, G.; *et al.* (Unite de Recherches de Pathologie Digestive, INSERM, 46 Chemin de La Gaye, 13009 Marseilles, France). *Am. J. Gastroenterol.* 66(3):221-240; 1976.

The effect of lidocaine, injected i.v. or applied topically to the duodenal pancreatic papilla, on secretin-induced pancreatic secretion was studied in 14 duodenal fistula dogs, 4 of which had been alcohol-fed for 2 yr. Lidocaine was also applied directly to the papilla or injected into dogs that had received secretin and cholecystokinin (CCK). Pancreatic secretion was measured by flow rate during 20 min, bicarbonate concentration and output, and protein concentration and output. Lidocaine applied topically to the duodenal pancreatic papilla inhibited pancreatic secretion but had the opposite effect in dogs administered CCK plus secretin. Chronic alcohol feeding enhanced the lidocaine-induced rise in pancreatic secretion in dogs given CCK and secretin. When lidocaine was injected i.v., no significant changes in pancreatic secretion were observed in nonalcoholic dogs. Effects similar to those of topically applied lidocaine were observed with i.v. lidocaine in alcoholic and nonalcoholic superimposed on CCK and secretin stimulation did not prevent and actually elevated the i.v. lidocaine-induced pancreatic secretion changes. It is postulated that lidocaine acts directly on the papilla by interrupting duodenopancreatic reflexes. Lidocaine may modify pancreatic secretion in the CCK- and secretin-stimulated animals by depressing an anti-CCK factor secreted by the small intestine.

0117 ROLE OF THE PANCREAS IN STABILITY OF MITOCHONDRIAL FUNCTION IN HEMORRHAGIC SHOCK. (Eng.) Sato, M.; Yamamoto, M.; Ozawa, K.; Honjo, I. (Dept. Surgery, Kyoto Univ., Kyoto, Japan). *J. Surg. Res.* 23(1):19-24; 1977.

The role of the pancreas in adenine nucleotide and mitochondrial metabolisms during hemorrhagic shock was studied in male Wistar rats. Pancreatectomized rats showed more rapid depletion of energy stores during hemorrhagic shock than did nonpancreatectomized animals. In pancreatectomized rats the oxidative and phosphorylative activities of the mitochondria decreased markedly to about 40% of the preshocked levels at 1 hr after hemorrhagic shock, although those in control rats remained almost unchanged. The decreases in mitochondrial oxidative and phosphorylative activities and hepatic energy charge levels in pancreatectomized rats were not restored by the reinfusion of the shed blood after 1-hr hemorrhagic shock. It is suggested that the pancreas plays an important role in hepatic energy metabolism during hemorrhagic shock, possibly due to maintaining the integrity of mitochondrial membrane.

0118 ULTRASTRUCTURAL AND FUNCTIONAL CHANGES IN PANCREATIC ACINAR CELLS DURING AUTOLYSIS. (Eng.) Nevalainen, T. J.; Anttinen, J. (Lab. Electron Microscopy, Univ. Turku, Kiinamyllynkatu 10, SF-20520 Turku 52, Finland). *Virchows Arch.* [*Cell Pathol.*] 24(3):197-207; 1977.

Ultrastructural changes during *in vitro* autolysis were studied in the rat pancreas. Tissue samples were incubated at 18-20 C in a moist atmosphere for 0, 0.5, 1, 3, 6, 12, and 24 hr. The disintegration of acinar cells began by swelling of various cell compartments and gradual breakdown of cell membranes. Zymogen granules remained morphologically intact for at least 3 hr. There were no signs of increased autophagic activity during the observation period. Myelin figures and other membranous remnants of disintegrated cells, together with individual cells and cell organelles whose morphology was relatively well preserved were seen even after 24 hr incubation. The secretory response of acinar cells to pancreozymin stimulation, as measured by amylase release into the incubation medium *in vitro*, decreased progressively, approaching zero, during the 12-hr autolysis. No active trypsin was detected in the tissue samples during the 24-hr observation time. It is concluded that, during hypoxic autolysis at room temperature between 18-20 C *in vitro*, acinar cell disintegration results from breakdown of cellular membranes and that autophagocytosis is not involved, that most zymogen granules remain morphologically intact, even at the time when cell membranes show evidence of damage, that no trypsin activation takes place in the tissue during hypoxic autolysis, and that the acinar cells are capable of responding to secretory stimulation for 3-6 hr after removal of the tissue from the experimental animal.

0119 PANCREATITIS FOLLOWING THE INTRADUCTAL INJECTION OF PARTIALLY PURIFIED ENTEROKINASE IN DOGS. (Eng.) Hammond, J. B.; Mann, N. S. (Veterans Admin. Lakeside Hosp., 333 E. Huron, Chicago, IL 60611). *Am. J. Dig. Dis.* 22(3):182-188; 1977.

To determine whether enterokinase (EK) alone can cause the experimental pancreatitis (PT) produced by proximal and distal closure of bile duct ligated dogs, saline suspensions of partially purified EK and other test materials were injected into the duct of Wirsung of dogs. After 24 hr, their pancreases were examined, and the increment in serum amylase was estimated. Following 0.5% EK administration, both PT and hyperamylasemia ensued; hyperamylasemia without PT occurred when EK was inactivated by heat, administered with trypsin inhibitor, or administered in more dilute solution. The injection of trypsin inhibitor or of hog gastric mucin also led to hyperamylasemia, but not to PT. It is concluded that the PT observed was due to EK activity and that EK could contribute to the production of PT in the closed duodenal loop model. The hyperamylasemia observed in the absence of PT is unexplained, but appears to be related to the colloidal properties of the materials injected.

0128 EFFECT OF FASTING ON THE BIOCHEMICAL PROPERTIES OF PERFUSED RAT LIVER. (Eng.) Lee, D.; Clark, D. G. (Univ. Otago Medical Sch., P.O. Box 913, Dunedin, New Zealand). *J. Surg. Res.* 23(1):43-49; 1977.

Livers from male Wistar rats that had been either fed *ad libitum* or fasted for 48 hr were perfused with bovine RBC in Krebs-Ringer buffer containing 3% bovine serum albumin, and their function was studied. There was little difference in the ability of livers from fed or fasted rats to produce bile. Livers from fed rats maintained their initial rate of urea synthesis (1.5 μmol/min) for 60 min, but livers from fasted rats maintained this rate for only 20 min. At the end of these periods, urea synthesis fell to 0.8 μmol/min and 0.6 μmol/min for livers from fasted and fed rats, resp. Potassium was released into the acellular fraction of the perfusate at a rate of 0.3 μEq/min 60 min after the start of perfusion of livers from fed rats and 20 min after the start of perfusion for fasted rats. Compared with unperfused controls, perfusion for 3 hr had little effect on the latency (62.2 ± 3.1% versus 60.5 ± 2.3% for controls) and sedimentability (62.6 ± 2.9% versus 68.0 ± 1.2% for controls) of β-glucuronidase or on the sedimentability (69.1 ± 2.2% versus 69.7 ± 0.7% for controls) of acid phosphatase in liver homogenates from fed rats. There was a significant decrease in latency of acid phosphatase (66.6 ± 1.7% versus 75.8 ± 1.8% for controls) in liver homogenates from fed rats. Perfusion of livers from fasted rats resulted in marked and statistically significant falls in the latency (46.4 ± 3.0% versus 72.8 ± 1.2% for controls) and sedimentability (56.4 ± 2.5% versus 78.1 ± 1.8% for controls) of acid phosphatase and in the sedimentability (53.4 ± 2.3% versus 65.7 ± 1.5% for controls) of β-glucuronidase. The fall in latency of β-glucuronidase (55.5 ± 1.7% versus 57.0 ± 1.9% for controls) was not statistically significant. It is concluded that the livers from fasted rats are less able to tolerate the stress of perfusion *in vitro* than livers from rats fed *ad libitum*.

0129 A MORPHOMETRIC STUDY OF THE INHIBITION OF AUTOPHAGIC DEGRADATION DURING RESTORATIVE GROWTH OF LIVER CELLS IN RATS RE-FED AFTER STARVA-

TION. (Eng.) Pfeifer, U.; Bertling, J. (Pathologisches Institut der Universitat, Josef-Schneider-Str. 2, D-8700 Wurzburg, W. Germany). *Virchows Arch.* [*Cell Pathol.*] 24(2):109-120; 1977.

The number of autophagic vacuoles (AV) in the liver cells of rats re-fed after starvation was quantitated. In the liver parenchymal cells of adult male rats re-fed on the evening of the fifth day after a period of absolute starvation, a nearly complete absence of AV was found by the morphometric determination of the fractional cytoplasmic volume of AV. The mean value for that parameter increased only gradually during periods of re-feeding. The value was found to be in the range of the control values only on, or after, the fifth day of re-feeding. As in previous experiments, in the control animals the number of AV was again found to be dependent on a circadian rhythm with maxima during the light, and minima during the dark, periods. This rhythm reappeared in the period of re-feeding without a shift in phase. In the controls as well as in the re-fed animals the "segregated fraction" was highest for microbodies, intermediate for mitochondria and glycogen, but rather low for the remaining components of the cytoplasm. It is suggested that long-term inhibition of cellular autophagy plays an important role in the restorative cellular growth of the liver during the recovery from the atrophy induced by starvation.

0130 HEPATIC HEMODYNAMICS IN AN EXPERIMENTAL ANIMAL WITH PARTICULAR REFERENCE TO HEPATIC ARTERY FLOW.

(Ger.) Thiel, H. (Med. Univ.-Klinik, Josef-Schneider-Strasse 2, 87 Wurzburg, W. Germany). *Fortschr. Med.* 95(27):1741-1744; 1977.

Hepatic and systemic hemodynamics were studied in healthy rats and rats with liver diseases, with particular emphasis on the regulation mechanism of the hepatic artery and compensatory changes of hepatic arterial blood flow. The trials were performed with the cardiac output fractionation technique in animals with portal hypertension (brought about in one of three ways: prehepatically after protracted occlusion of the portal vein, intrahepatically following cirrhosis induced by choline-deficient diet or carbon tetrachloride, or by granulomatous hepatitis induced by SiO_2 particles). The experiments were also carried out in animals with galactosamine hepatitis, rats with portacaval shunt, in regenerating rat liver after partial hepatectomy, and in rats with artificial systemic endotoxemia. Hepatic arterial blood flow in both the normal and abnormal liver was regulated by a venovasomotor reaction (after portacaval end-to-side shunt) and systemically by autoregulation. As portal liver blood flow decreased, hepatic arterial flow increased, especially after portacaval end-to-side shunt. However, this increase did not fully compensate for the diverted portal venous blood flow. A significant rise in circulating blood volume as a result of hemodilution was noted in protracted occlusion of the portal vein, in CCl_4-induced cirrhosis, and SiO_2-induced granulomatous hepatitis. A definite relation was noted between the elevation of circulating blood volume and the extent of portacaval shunt volume. Cardiac output and partial circulating times also showed a close relation to the extent of portacaval shunt flow.

0131 THE HEPATIC ARTERY: SUBSERVIENT TO HEPATIC METABOLISM OR GUARDIAN OF NORMAL HEPATIC CLEARANCE RATES OF HUMORAL SUBSTANCES.

(Eng.) Lautt, W. W. (Dept. Physiology, Univ. Saskatchewan, Saskatoon, Saskatchewan, Canada). *Gen. Pharmacol.* 8(2): 73-78; 1977.

Studies indicating that local tissue demands (at least within physiological limits) do not affect hepatic arterial flow and that the hepatic artery is not affected by metabolites or local hypoxia are reviewed. With the use of an electromagnetic flowmeter, a method by which uptake or output of bloodborne substances can be determined simultaneously with hemodynamic measurements of the intact liver was developed. O_2 delivery to cat liver was reduced to 68% of control; in spite of a marked reduction of O_2 content and O_2 pressure in the venous blood, no arterial vasodilation was seen, although the arteries supplying the gut did dilate. Thus, the hepatic artery is not subservient to local hepatic needs, at least within the limits examined. Other studies have shown that decreases in hepatic metabolism are not accompanied by decreased hepatic blood flow. It is suggested that the hepatic artery serves to maintain blood flow *per se* constant (as opposed to O_2 delivery). The significance of constant hepatic blood flow is indicated by the fact that altered hepatic blood flow produces altered rates of hepatic clearance of many substances. By compensating for wide fluctuations in portal venous flow, the hepatic artery prevents equally wide fluctuations in hepatic clearance rates of endogenous substances. The constancy of hepatic clearance rates thereby prevents wide swings in plasma hormone levels that would otherwise be finely controlled only by altered rates of synthesis and release from the endocrine glands. The hepatic artery is thus proposed to be subservient not to the liver but rather to the needs of the entire organism, and it is an essential component in the maintenance of stable levels of substances cleared by the liver.

0132 ENZYMATIC ELIMINATION OF SUBSTRATES FLOWING THROUGH THE INTACT LIVER.

(Eng.) Bass, L.; Keiding, S.; Winkler, K.; Tygstrup, N. (Dept. Mathematics, Univ. Queensland, Australia). *J. Theor. Biol.* 61(2):393-409; 1976.

Enzymatic elimination of a class of substrates by the liver is theoretically analyzed in terms of a convective model of the hepatic microcirculation carrying the substrates. The class of elimination reactions considered is represented by the irreversible phosphorylation of D-galactose by galactokinase; D-galactose is important as a diagnostic substance in liver disease. A model liver is considered that consists of a large number of tubes arranged in parallel, each corresponding to one sinusoid with its unidirectional blood flow and its adjoining parenchymal cells containing enzyme. The total blood flow through the liver and the total maximum elimination rate (Vmax) receive equal contributions from all sinusoids. The half-saturation concentration of the relevant substrate (Km) is the same throughout the model. The convective model establishes connections between the inflow and outflow substrate concentrations, the total blood flow, and the overall substrate elimination rate. The two kinetic parameters Vmax and Km are involved as constants to be inferred for each liver from the above four observable parameters. The model is used to predict the time course of galactose concentration in the hepatic artery and vein of a patient with liver disease after a single i.v. injection of galactose. The model shows a capacity of the liver to compensate in part for the effects of disease (loss of Vmax) by an increase in biochemical efficiency. The model is also tested and validated on four prolonged near-steady states that were established on a perfused isolated pig liver by controlled galactose infusions.

0133 QUANTITATION OF PATHWAYS OF ETHANOL METABOLISM.

(Eng.) Havre, P.; Abrams, M. A.; Corrall, R. J. M.; Yu, L. C.; Szczepanik, P. A.; Feldman, H. B.; *et al.* (Case Western Reserve Univ., Sch. Medicine, Cleveland, OH 44106). *Arch. Biochem. Biophys.* 182(1):14-23; 1977.

A method for estimating the sum of the contributions to ethanol oxidation by the microsomal ethanol-oxidizing system (MEOS) and by catalase in the intact liver cell is described. It depends upon a comparison of the fate of the *R* hydrogen of ethanol and the hydrogen bound to carbon-2 of sorbitol under identical conditions. One limitation of this method is that it is based on the assumption that isotopic discriminations are similar for alcohol dehydrogenase, MEOS, and catalase. For either or both the MEOS and catalase oxidations, there may be much greater isotopic discrimination than for alcohol dehydrogenase, so that ^3H conversion to ^3H_2O by either of these pathways finds relatively little expression in the data. Using incubation of liver slices from rat and monkey at an ethanol concentration of 3 mg/ml, and from rat at 1 mg/ml, alcohol dehydrogenase catalysis was found to account for an average of 89% or more of the initial metabolism of ethanol. The stereospecificity of the sorbitol dehydrogenase-catalyzed reaction was shown to be of the A type in the rat. Sorbitol oxidation in the intact liver cell was found to be irreversible.

0134 METABOLIC CONSEQUENCES OF ALCOHOL CONSUMPTION.

(Eng.) von Wartburg, J. P. (Medizinisch-chemisches Institut der Universitat Bern, Buhlstrasse 28, CH-3012 Bern, Switzerland). *Nutr. Metab.* 21(1/2/3):153-162; 1977.

The metabolism of alcohol is reviewed. The metabolic effects of alcohol are closely related to organic as well as societal aspects of alcoholism. Individual differences in the biologic sensitivity to ethanol are thought to represent important features underlying these afflictions. The results of recent biomedical research provide evidence for a biochemical individuality with respect to the enzymes involved in alcohol metabolism. Human liver alcohol dehydrogenase, the principle ethanol oxidizing enzyme in man, exists in multiple molecular forms (isoenzymes). In addition, a genetic polymorphism (atypical variant) is observed. Large racial differences are found for the prevalence of the variant enzyme, which is characterized by a high specific activity. Possible relationships of the individual isoenzyme pattern of alcohol dehydrogenase and of other alcohol metabolizing enzymes to the nature and extent of metabolic effects of ethanol are discussed.

0135 METABOLIC AND HEPATIC EFFECTS OF ALCOHOL.

(Eng.) Isselbacher, K. J. (Harvard Medical Sch., Boston, MA 02114). *N. Engl. J. Med.* 296 (11):612-616; 1977.

Effects of alcohol on carbohydrate, protein, amino acid, and lipid metabolism are discussed and some disorders associated with alcoholism are reviewed. Alcohol inhibits gluconeogenesis and can lead to hypoglycemia if there is a substantial depletion of liver glycogen. Galactose oxidation is also inhibited by alcohol, although this is not usually clinically apparent. Albumin and transferrin synthesis are inhibited by alcohol, while lipoprotein synthesis is stimulated; this latter effect may contribute to the hypertriglyceridemia associated with alcohol ingestion. The major effects of alcohol ingestion on lipid metabolism are hypertriglyceridemia and fatty liver, resulting from the stimulation of serum and liver triglycerides. The increased NADH-NAD ratio induced by alcohol ingestion leads to increased lactate production, resulting in hyperuricemia; increased delta-aminolevulinic acid synthesis, leading to increased porphobilinogen production; and decreased citric acid cycle activity. Other effects induced by alcohol include increased acetaldehyde levels in the blood and tissues, decreased serum magnesium and phosphate, increased catecholamine release leading to decreased beta-adrenergic-receptor sensitivity, increased oxygen consumption, and ketoacidosis. The pathogenesis of ketoacidosis may involve hormonal factors and enhanced generation of NADH. The ability of alcohol to decrease the intestinal absorption of sugars, amino acids, calcium, folic acid, vitamin B_{12}, and other nutrients may contribute to the impairment in nutrition that is frequently present in alcoholic patients. Recent observations may explain the morphological alterations seen in alcoholic hepatitis. Hepatocyte ballooning may involve hypoxemia (produced by the hypermetabolic state induced by alcohol), alcohol-induced retention of export proteins by the liver, and the antitubular action of alcohol. Collagen probably plays an important role in the development of cirrhosis.

0136 ETHANOL METABOLISM BY A TRANSPLANTABLE HEPATOCELLULAR CARCINOMA: ROLE OF MICROSOMES AND MITOCHONDRIA. (Eng.) Cederbaum, A. I.; Becker, F. F.; Rubin, E. (Mount Sinai Sch. Medicine, City Univ. New York, New York, NY 10029). *J. Biol. Chem.* 251(17):5366-5374; 1976.

Ethanol metabolism was studied in rat hepatocellular carcinoma 252 (HC-252), and the effects of the activity of alcohol dehydrogenase, of the activity of the substrate shuttles, of the ability of the mitochondria to oxidize reducing equivalents, and of the activity of the microsomal ethanol-oxidizing system on this process were investigated. Ethanol metabolism in slices or homogenates of the transplantable carcinoma was 50-60% of the rate found in host liver slices or homogenates when they were expressed per gram of tissue wet weight and 70-80% of the liver when the rates were expressed per milligram of tissue protein. At 10 mM ethanol, the activities of alcohol dehydrogenase in tumor and liver supernatants were comparable. Tumor microsomes did not oxidize ethanol in the presence of a NADPH-generating system, indicating the absence of the microsomal ethanol-oxidizing system and catalase-mediated peroxidation of ethanol. The HC-252 microsomes were contaminated with catalase, and acetaldehyde production occurred in the presence of a H_2O_2-generating system (xanthine oxidase). The virtual absence of ethanol oxidation and drug metabolism (aminopyrine demethylase and aniline hydroxylase) in HC-252 microsomes may be due to the low activities of NADPH-cytochrome c reductase, NADPH oxidase, and NADPH-dependent oxygen uptake. Microsomal oxidation of ethanol was present in the well-differentiated tumor, Morris hepatoma 5123C, while activity was negligible in microsomes from Morris hepatoma 7288CTC, a less differentiated tumor. Microsomal NADPH oxidase was present in the well differentiated tumor 5123C, but was lacking in the less differentiated tumor 7288CTC. Several microsomal, mitochondrial, and cytosolic properties of HC-252 were similar to those of Morris hepatoma 7288CTC, but differed from those of the more differentiated 5123C tumor and normal liver. The content of mitochondrial protein in HC-252 was only 25% that of liver, and oxygen consumption was only 28% that of the liver. When corrected for the mitochondrial protein content, oxygen uptake in tumor HC-252 and liver homogenates was comparable. Isolated tumor and liver mitochondria displayed comparable state 4 and 3 rates of oxygen consumption with succinate and glutamate as substrates. The activities of the reconstituted malate-aspartate and α-glycerophosphate shuttles were only slightly lower in isolated HC-252 mitochondria than in liver mitochondria. Antimycin inhibited alcohol metabolism, and pyruvate stimulated alcohol metabolism, ism, and pyruvate stimulated alcohol metabolism, much less in tumor slices than in liver slices, suggesting the presence of an augmented mitochondria-independent, cytosolic mechanism for oxidizing reducing equivalents in the tumor. These factors suggest that oxidation of NADH is the limiting factor in ethanol metabolism. Whereas, in the liver mitochondrial reoxidation is predominant, in HC-252, cytosolic reoxidation of NADH also plays a major role.

0137 THE INFLUENCE OF CHRONIC ETHANOL FEEDING TO RATS ON THE INTEGRITY OF LIVER MITOCHONDRIAL MEMBRANE AS ASSESSED WITH THE Mg^{2+}-STIMULATED ATPase ENZYME. (Eng.) Hosein, E. A.; Hofmann, I.; Linder, E. (Dept. Biochemistry, McGill Univ., Montreal, Quebec H3G 1Y6, Canada). *Arch. Biochem. Biophys.* 183(1):64-72; 1977.

Mg^{2+}-stimulated ATPase, used as an indicator of liver mitochondrial membrane damage by ethanol in Sprague-Dawley rats was compared in two mitochondrial preparations using substrate concentrations that gave near V activity. Results obtained with this enzyme using different temperature and substrate concentrations showed that ethanol treatment to rats had affected both the activity of this enzyme and the liver inner mitochondrial membrane. This was evidenced by the appearance of a phase-transition temperature at 32 C in Arrhenius plots of samples from the alcoholic liver but not from the control liver. It was observed that when the assay was carried out below 26 C, mitochondria from rats treated chronically with ethanol had diminished ATPase activity. In mitochondrial ghosts, chronic ethanol feeding caused a decrease in the phase-transition temperature observed in Arrhenius plots, usually associated with the lipid phase transition, from the normal value of 18.5 ± 0.2 to 15.8 ± 0.3 C in the alcoholic rats. A similar decrease in phase-transition temperature was also obtained with sonicated liver mitochondrial membrane preparations from chronically ethanol-fed rats compared with chow-fed controls. Throughout the entire range of temperatures used, the activation energies of the control and chronic alcoholic mitochondrial preparations were different. These results affirm that chronic ethanol treatment alters the liver mitochondrial membrane structure or enzyme microenvironment, which, in turn, may affect mitochondrial function.

0138 EFFECT OF TEMPERATURE ON THE ASSAY OF HEPATIC ALCOHOL DEHYDROGENASE. (Eng.) Carter, E. A.; Isselbacher, K. J. (Harvard Medical Sch., Boston, MA 02114). *Proc. Soc. Exp. Biol. Med.* 155(3):290-295; 1977.

The effect of assay temperature (T) on alcohol dehydrogenase (ADH) activity was investigated in rat and horse liver supernatants and purified horse liver, yeast, and human liver ADH. The assay mixture consisted of 50 mM glycine-NaOH buffer (pH 9.6), 50 mM ethanol, 1.5 mM NAD, and 0.1 ml of ADH-containing fraction. By raising the T from 25 to 60 C, the ADH activity of rat and horse liver supernatants was stimulated eight- and threefold, resp. At 55 C, purified human liver ADH activity was 2.5 times greater, and purified horse liver activity two times greater. Hepatic ADH was not stimulated if the heated samples were allowed to cool to room T before ethanol was added and the assay was then carried out at 25 C. Purified yeast ADH activity was inhibited at T's >45 C. The stimulating effect of increased T may involve changes in enzyme function. When 2-butanol and 2-butanone were used as substrates, ADH activity was enhanced equally in both the forward and reverse directions. Increasing the T from 25 to 60 C increased the reduction of 17-β-hydroxy-5-β-androstan-3-one with NADH fivefold (from 13.9 to 63.3 nmol NADH oxidized/mg protein/min). Only at 50-60 C could ADH activity be detected in normal rat or human plasma. At 50 C, this activity (nmol NADH formed/ml plasma/10 min) increased from 30 to 85 and 118 at 1.5 and 3 hr, resp., after the administration of CCl_4 (2 ml/kg intragastrically) and from 8.9 to 14.4 after chronic ethanol feeding (5% of a liquid diet for 10 days). The increased sensitivity obtained by measuring plasma ADH activity at 50 C may make this assay useful for studying patients with liver injury.

0139 THE ROLE OF CYTOCHROME P-450 IN THE HYDROPEROXIDE-CATALYZED OXIDATION OF ALCOHOLS BY RAT-LIVER MICROSOMES.

(Eng.) Rahimtula, A. D.; O'Brien, P. J. (Dept. Biochemistry, Memorial Univ. Newfoundland, St. John's, Newfoundland A1C 5S7, Canada). *Eur. J. Biochem.* 77(1):201-208; 1977.

The roles of the microsomes of cytochrome P-450 and of catalase in hydroperoxide-catalyzed ethanol oxidation was investigated in rat liver microsomes. When cumene hydroperoxide was the oxidizing agent, the pH optimum for microsomal ethanol oxidation was approximately 8.0, while the catalase-dependent reaction showed no pH optimum within the range of pH 6.5-9.0 but increased with increasing pH. Both catalase and the microsomes gave an apparent Km for ethanol in the region of 4-9 mM, but the microsomes gave an additional Km for ethanol in the region of 40-75 mM. In the microsomes, the two Km values were obtained even in the presence of 0.1 mM hydroxylamine, suggesting that the lower Km of 4-9 mM is not due to the small amount of catalase present in the microsomes. Catalase and microsomes also behaved differently in the presence of several inhibitors. In general, cytochrome P-450-specific agents (e.g., metyrapone and hexobarbital) inhibited the microsomal reaction, while they had no effect on the catalase-dependent reaction. Catalase-specific inhibitors (e.g., aminotriazole and hydroxylamine) inhibited the catalase-dependent oxidation but not the microsomal reaction. Phenobarbital pretreatment of the rats raised the specific activity of cumene hydroperoxide-dependent ethanol oxidation per milligram of microsomes by 7.2-fold. These results indicate that, in addition to catalase, another enzyme, presumably cytochrome P-450, is responsible for cumene hydroperoxide-dependent ethanol oxidation. When H_2O_2 replaced cumene hydroperoxide as the oxidizing agent, ethanol oxidation was not increased by phenobarbital induction and was inhibited by hydroxylamine but not by metyrapone. These results indicate that the microsomal system behaves more like catalase in H_2O_2-catalyzed oxidation, suggesting that the microsomal catalase is responsible for H_2O_2-dependent ethanol oxidation.

0140 INFLUENCE OF ETHANOL OXIDATION RATE ON THE LACTATE/PYRUVATE RATIO AND PHOSPHORYLATION STATE OF THE LIVER IN FED RATS.

(Eng.) Poso, A. R.; Forsander, O. A. (Res. Lab. of the State Alcohol Monopoly, Alko, Box 350, SF 00101 Helsinki 10, Finland). *Acta Chem. Scand.* [*B*] 30(9):801-806; 1976.

To determine if the cytosolic redox changes induced by ethanol are reflected in the cytosolic phosphorylation state, the effect of the ethanol oxidation rate on the interaction between the phosphorylation state (the [ATP]/[ADP] x $[HPO_4]^{2-}$ ratio) and the redox state (the free $[NAD^+]$/[NADH] ratio) of the liver cytosol was studied in intact, fed, female Sprague-Dawley rats. The rate of ethanol oxidation was inhibited to different degrees; with 0, 0.1, 0.5, 1.0, and 2.0 mmol/g pyrazole, the ethanol oxidation rates were 4.6, 4.1, 3.6, 3.4, and 2.3 μmol/g liver (wet weight)/min, resp. The ethanol oxidation rate had no influence on the liver lactate level, but correlated significantly with the pyruvate level. Accordingly, a significant correlation was also found between the ethanol oxidation rate and the lactate/pyruvate ratio. The rate of ethanol oxidation correlated significantly with the liver 3-phosphoglycerate level. No change in the glyceraldehyde-3-phosphate level was found. No correlation was found between the ethanol oxidation rate and the glyceraldehyde-3-phosphate/3-phosphoglycerate redox couple. Ethanol administration slightly increased the liver ATP level, but the simultaneous administration of pyrazole eliminated this effect. Other adenine nucleotides and HPO_4^{2-} were not changed. The changes in the rate of ethanol oxidation had no effect on the phosphorylation state in the fed liver. It is assumed that in the fed liver the phosphorylation state is so well stabilized that the redox level has no influence.

0141 ATP METABOLISM IN AN ETHANOL INDUCED FATTY LIVER.

(Eng.) Gordon, E. R. (Montreal General Hosp., Montreal, Canada). *Biochem. Pharmacol.* 26(13):1229-1234; 1977.

The mechanism responsible for the decrease in phosphate potential in the liver of rats fed ethanol for prolonged periods was determined. Changes in ATP utilization were assessed by measuring the activity of the $[Na^+ + K^+]$-activated ATPase system, and changes in ATP synthesis were assessed by determining the activity of the adenine nucleotide translocase (ANT) system. Since long-chain coenzyme A (CoA) derivatives of fatty acids regulate the translocation of ADP into mitochondria, their total cellular content and mitochondrial level were also determined. After 2 weeks on a liquid diet in which 36% of the caloric intake was ethanol, male Sprague-Dawley rats developed a fatty liver. This change was not associated with any significant alteration in hepatic ATP content or in the activity of the ANT system. After 4 weeks, excess neutral lipid in the liver still persisted, but it was associated with a marked increase in the level of long-chain CoA fatty acid derivatives. The hepatic ATP level was only 50% of normal, and the rate of translocation of ADP into the mitochondria was decreased. The activity of the ANT system was restored to normal values if the long-chain CoA fatty acid derivatives were removed from the surface of the mitochondrial membrane by treatment of the preparation with defatted albumin. At this time, there was only a slight (15%) enhancement of the $[Na^{+}+K^{+}]$-activated ATPase system. With the removal of ethanol from the diet, the ATP level quickly returned to normal. Changes in the hepatic ATP level correlated well with the activity of the ANT system, but they did not parallel changes in the activity of the Na^{+} pump system. These findings indicate that the dominant feature leading to the decrease in the ATP/ADP x P_i ratio is a decreased synthesis of ATP.

0142 STUDIES IN THE ETHANOL-INDUCED CHANGES IN GLYCEROLIPID SYNTHESIS IN RATS AND THEIR PARTIAL REVERSAL BY n-(2-BENZOYLOXYETHYL)NORFENFLURAMINE (BENFLUOREX).

(Eng.) Pritchard, P. H.; Brindley, D. N. (Univ. Hosp. and Medical Sch., Clifton Blvd., Nottingham NG7 2UH, England). *J. Pharm. Pharmacol.* 29(6):343-349; 1977.

The hypothesis that benfluorex (S-780) might reverse the ethanol-induced synthesis of hepatic triacylglycerol (TG) was tested, and the effects of ethanol and S-780 on lipid metabolism were studied. Male Wistar rats were treated daily for 5 days with S-780 (50 mg/kg), and 2 hr after the fifth treatment they were intubated with ethanol (5 g/kg) or with isocaloric glucose. S-780 did not alter the absorption or oxidation of $[1-^{14}C]$ethanol, nor did it decrease the concentration of ethanol and its water soluble metabolites in the tissues examined. The rate of hepatic glycerolipid synthesis was measured *in vivo* using $[^{14}C]$palmitate and $[^{3}H]$glycerol, and the accumulation of $[^{14}C]$palmitate in various tissues was determined 4 hr after i.v. injection. Ethanol treatment increased the relative rate of hepatic TG synthesis and decreased the synthesis of phosphatidylcholine (PC), phosphatidylethanolamine (PE), and phosphatidylserine plus phosphatidylinositol (PS + PI). The relative flux from phosphatidate (PA) to diacylglycerol (DG) and TG was increased. These changes were reflected in the accumulation of $[^{14}C]$palmitate in hepatic lipids and were obtained under conditions where the net rate of $[^{14}C]$palmitate oxidation to $^{14}CO_2$ was greater in those rats treated with ethanol instead of glucose. S-780 did not alter the oxidation rates over a 4-hr period. Ethanol treatment increased the accumulation of $[^{14}C]$palmitate in the PS + PI fraction of lung and decreased the proportion in PE. In the kidney, it increased the concentration of $[^{14}C]$palmitate in TG, DG, and PE and decreased the concentration in PC and PS + PI. Pretreatment of the rats with S-780 partially reversed the changes in palmitate accumulation in glycerolipids caused by ethanol. S-780 treatment also decreased the rate of hepatic TG synthesis from glycerol in the rats fed glucose. It increased the percentage recovery of $[^{14}C]$palmitate in the livers and kidneys of glucose-fed rats and decreased that in adipose tissue. This treatment decreased the proportion of $[^{14}C]$palmitate recovered in the TG of the kidneys and lungs of these rats and increased the proportion in PI + PS. The results show that S-780 interferes with the balance between phospholipid and TG synthesis *in vivo*. It produces a decrease in the synthesis and accumulation of TG in rats treated both with ethanol and glucose.

0143 LIPID PEROXIDATION IN ISOLATED HEPATOCYTES FROM RATS INGESTING ETHANOL CHRONICALLY.

(Eng.) Remmer, H.; Albrecht, D.; Kappus, H. (Institut fur Toxikologie, Universitat Tubingen, Wilhelmstrasse 56, D-7400 Tubingen, W. Germany). *Naunyn Schmiedebergs Arch. Pharmacol.* 298(2):107-113; 1977.

The role of lipid peroxidation in ethanol-induced liver damage was investigated. Isolated hepatocytes from rats consuming ethanol (8.5 g/kg) daily produced twice as much malondialdehyde as liver cells from control animals. The release of LDH and the uptake of trypan blue in both control and test hepatocytes did not differ during the incubation period of 2 hr. Glutamate dehydrogenase (GLDH), however, was only set free into the medium from liver cells of ethanol-drinking rats, indicating that mitochondrial alterations are involved. Bromotrichloromethane ($CBrCl_3$) promoted lipid peroxidation in hepatocytes from ethanol-drinking rats to a much greater degree than in cells from control rats. The cell damage induced by $CBrCl_3$, indicated by a release of LDH and GLDH from the hepatocytes and by hepatic uptake of trypan blue was also much more pronounced in liver cells from ethanol-drinking animals. The stronger action of $CBrCl_3$ cannot be explained by an enhanced microsomal metabolism, because no increase of drug metabolizing enzymes was observed. The relatively low ethanol consumption did not influence body growth and liver weight and did not evoke any triglyceride accumulation. The normal balance between processes favoring lipid peroxidations and reactions protecting the liver cells seems to be shifted during alcohol intake to a state that promotes radical formation

0144 ROLE OF ACETALDEHYDE IN THE ETHANOL-INDUCED IMPAIRMENT OF GLYCOPROTEIN METABOLISM IN RAT LIVER SLICES.

(Eng.) Sorrell, M. F.; Tuma, D. J.; Schafer, E. C.; Barak, A. J. (Veterans Admin. Hosp., 4101 Woolworth Ave., Omaha, NB 68105). *Gastroenterology* 73(1):137-144; 1977.

The mechanism responsible for ethanol-induced changes in the glycosylation of proteins was investigated in rat liver slices. Ethanol (5-50 mM) decreased $[1-^{14}C]$glucosamine and $[^{14}C]$leucine incorporation into total liver and microsomal proteins and greatly inhibited incorporation into medium (secretory) proteins. Pyrazole (4 mM) prevented the inhibition of glycoprotein synthesis by ethanol. Additions of methylene blue or pyruvate, which corrected the disordered redox state caused by ethanol oxidation, did not reverse the inhibitory effects of ethanol on glycosylation. Sorbitol also inhibited glycosylation; however, fructose similarly inhibited glycoprotein synthesis without altering the redox state. When low levels of acetaldehyde (0.12-0.70 mM) were maintained in the medium by means of infusion, a significant inhibition of glycoprotein synthesis was observed. Acetate did not impair glycosylation. These data suggest that the ethanol-induced impairment of glycoprotein synthesis and secretion is a consequence of ethanol metabolism and further suggest that this inhibition is attributable to acetaldehyde formation rather than to the altered redox state resulting from ethanol oxidation.

0145 EFFECT OF A LOW-PROTEIN DIET ON ACETALDEHYDE METABOLISM IN RATS. (Eng.)

Lindros, K. O.; Pekkanen, L.; Koivula, T. (Res. Lab. of the State Alcohol Monopoly, Box 350, SF-00101 Helsinki 10, Finland). *Acta Pharmacol. Toxicol.* 40(1):134-144; 1977.

The effect of dietary changes on liver alcohol and aldehyde dehydrogenase activities, as related to effects on ethanol and acetaldehyde metabolism, was investigated in male Sprague-Dawley rats. Feeding for 8 weeks on diets rich in carbohydrate or fat, but with normal protein content, induced minor changes relative to giving a balanced diet. A low-protein, high-carbohydrate diet (5% and 80% of calorie content, resp.) caused a significant ($p<0.001$) reduction of both alcohol and aldehyde dehydrogenase activities in the liver. The activity of the high K_m aldehyde dehydrogenase in the microsomal and soluble fractions appeared to be more reduced than that of the low K_m enzyme in the mitochondrial fraction. The blood acetaldehyde level was significantly ($p<0.001$) higher in rats on the protein-deficient diet in spite of their reduced ethanol elimination rates. The results suggest that protein deficiency deranges acetaldehyde metabolism and may thus increase the possible contribution of acetaldehyde to the effects caused by ethanol metabolism.

0146 KINETICS OF SHEEP-LIVER CYTOPLASMIC ALDEHYDE DEHYDROGENASE. (Eng.)

MacGibbon, A. K. H.; Blackwell, L. F.; Buckley, P. D. (Dept. Chemistry, Massey Univ., Palmerston North, New Zealand). *Eur. J. Biochem.* 77(1):93-100; 1977.

The steady-state parameters of aldehyde oxidation were studied in sheep. Sheep liver cytoplasmic aldehyde dehydrogenase showed little pH dependence of V or k_{cat}. Some buffer anion effects were noted. The oxidation of aldehydes at pH 7.6 was quantitative, but irreversible. The initial velocity data indicated a sequential mechanism for the addition of substrates. Inhibition by NADH and the product analogue 2-bromo-2-phenylacetic acid, together with the known tight binding of NADH to the free enzyme, indicated an ordered mechanism with NAD^+ as leading substrate. Values for the rate of binding and dissociation of NAD^+ were obtained from the steady-state data. The values obtained were identical with those calculated from the data for the horse liver cytoplasmic enzyme. Close similarities are, in general, apparent for the horse and sheep liver cytoplasmic enzymes and with other tissue aldehyde dehydrogenases. Apparent substrate activation was observed with high concentrations of both acetaldehyde and propionaldehyde, a limiting value of 0.25/sec being obtained for k_{cat}. No isotope effect was observed on V using 1-^2H-propionaldehyde as substrate, suggesting that NADH release might be rate-limiting in the steady-state.

0147 ENZYMATIC DETERMINATION OF BILE ACIDS. THE NADP-SPECIFIC 7α-HYDROXYSTEROID DEHYDROGENASE FROM P. testosteroni (ATCC 11996). (Eng.)

Skalhegg, B. A.; Fausa, O. (Dept. Biochemistry, Nyegaard and Co. A/S, Nycovn. 2, Oslo 4, Norway). *Scand. J. Gastroenterol.* 12(4):433-439; 1977.

Using the specific substrates 7α-hydroxy-5β-cholanic acid and 3α,7α,12α-trihydroxy-3,12-diacetyl-5β-cholanic acid methyl ester, crude extracts of *Pseudomonas testosteroni* grown on a steroid-containing medium were shown to exhibit 7α-hydroxysteroid:NADP-oxidoreductase activity. The enzyme was highly specific for NADP. Both free and conjugated 7α-hydroxy bile acids could act as substrates, but those of low polarity (few hydroxyl groups) seemed to be preferred, judging from initial reaction velocity studies. The optimal conditions appeared to be at pH 8.5-9.5 and at 25 C. Free sulfhydryl groups were essential for maximum catalytic activity, since the enzyme was inhibited by sulfhydryl-reacting substances such as *p*-chloromercuribenzoate and monoiodoacetic acid. The ketone-trapping agents, hydrazine hydrate and semicarbazide, acted as inhibitors. Upon dilution, the storage stability was severely reduced, but this effect was counteracted by the addition of glycerol at at concentration of 20% or more. Gel filtration experiments on Sephadex G-100 indicated that the molecular weight was about 80,000. Thus, when this enzyme is used for bile acid determination in different biological fluids, a 60-min incubation time at pH 8.5-9.5 and 25 C should be used. Sulfhydryl-reacting substances should be avoided, and EDTA should be included in the assay mixture to chelate heavy metal ions.

0148 EFFECTS OF CHRONIC CHOLERETIC INFUSIONS OF BILE ACIDS ON THE MEMBRANE OF THE BILE CANALICULUS: A BIOCHEMICAL AND MORPHOLOGIC STUDY. (Eng.)

Nemchausky, B. A.; Layden, T. J.; Boyer, J. L. (SDTU Veterans Admin. Hosp. Hines, Hines, IL 60141). *Lab. Invest.* 36(3):259-267; 1977.

To determine whether choleretic infusions of bile acids modify the function or structure of the bile canalicular membrane, sodium taurocholate (NaTc) or dehydrocholate (DHC) was infused into male rats at a rate of 80 µmol/hr over an 18-hr period. Bile was collected by fistula, and phospholipid and cholesterol content was measured in bile, liver homogenates, and isolated liver plasma membranes (LPM) enriched in bile canaliculi. Na^-,K^+-ATPase, Mg^{2+}-ATPase, 5'-nucleotidase, and alkaline phosphatase activities were also measured in LPM. NaTc infusions enhanced cholesterol and phospholipid output in the bile (0.35 ± 0.12 and 3.40 ± 1.13 nmol/min/g before infusion for cholesterol and phospholipid, resp.; 1.17 ± 0.39 and 10.04 ± 3.94 nmol/min/g after infusion; $p<0.001$ in both cases) in association with a significant increase in phospholipid in both LPM and liver homogenates. Although DHC infusions resulted in a comparable excretion of bile acid, phospholipid, and cholesterol, output in bile did not increase from control values, and the concentration of these lipids in LPM and liver homogenates also did not change. However, LPM Na^+, K^+-ATPase significantly increased after DHC infusions compared to NaTc-infused animals or controls. Neither bile acid altered the activities of Mg^{2+}-ATPase, 5'-nucleotidase, or alkaline phosphatase. Both bile acids increased the diameter of the bile canalicular lumen as assessed by scanning electron microscopy, and produced irregularities and outpouchings in the canalicular membrane. Diverticuli and loss of microvilli were most prominent with DHC infusions, but canalicular side branching and the density of microvilli either remained unchanged or increased following NaTc infusions. Although the morphologic findings are qualitative, the results indicate that chronic choleretic infusions of NaTc and DHC have divergent effects, not only on enzyme activities in LPM, but also on phospholipid composition and three-dimensional structure. These findings suggest that bile acids may alter biliary secretion through their osmotic effects and by modifying lipids and enzymes in the bile canalicular membrane.

0149 PROLONGED INDUCTION OF GERMFREE BILE ACID PATTERN IN CONVENTIONAL RATS BY ANTIBIOTICS.

(Eng.) Gustafsson, B. E.; Gustafsson, J. A.; Carlstedt-Duke, B. (Dept. Germfree Res., Karolinska Institutet, Stockholm, Sweden). *Acta Med. Scand.* 201(3):155-160; 1977.

The duration of the germfree pattern of fecal bile acids was studied in male conventional rats following the administration of antimicrobial drugs. The rats received benzylpenicillin, neomycin, kanamycin, erythromycin, bacitracin plus neomycin, succinylsulfathiazole, or metronidazole (360,000 IU/kg, 180 mg/kg, 35 mg/kg, 360 mg/kg, 27,000 IU and 550 mg/kg, 360 mg/kg, or 20 or 100 mg/kg, resp.) by stomach tube for 5 days. Total fecal bile acids were analyzed in samples collected during periods of 3 days during the pretreatment period and during the 8 weeks following drug treatment. Metronidazole or succinylsulfathiazole had no or minor effects on the conventional bile acid pattern and the "bile acid index" (β-muricholic acid/deoxycholic acid) remained low. Benzylpenicillin, neomycin, or kanamycin induced a germfree bile acid pattern, i.e., increased the relative amounts of α- and β-muricholic acid in feces and eliminated deoxycholic acid and hyodeoxycholic acid from feces. The high bile acid index was normalized within 3 weeks after the termination of drug treatment, but the excretion of α- and β-muricholic acid was not normalized until a normal flora had been established by giving an enema with intestinal contents from intact, conventional rats. Treatment with erythromycin or bacitracin plus neomycin also produced a germfree bile acid pattern. In these cases, the bile acid index did not normalize after 5-8 weeks, and the excretion of the muricholic acids was not normalized until an enema with intestinal bacteria had been given. It is suggested that these long-lasting effects of antibiotics on the metabolism of bile acids in the intestinal tract should be considered after short-term antibiotic therapy in humans.

0150 DISSOLUTION RATES OF MODEL GALLSTONES IN HUMAN AND ANIMAL BILES AND IMPORTANCE OF INTERFACIAL RESISTANCE.

(Eng.) Molokhia, A. M.; Hofmann, A. F.; Higuchi, W. I.; Tuchinda, M.; Feld, K.; Prakongpan, S.; *et al.* (Coll. Pharmacy, Univ. Michigan, Ann Arbor, MI 48109). *J. Pharm. Sci.* 66 (8):1101-1105; 1977.

Cholesterol monohydrate dissolution kinetics in human gallbladder bile were studied to determine the magnitudes of the *in vitro* dissolution rates, the rate resistances in human gallbladder bile, and the extent that the interfacial resistance is the rate determining factor. Dissolution rate studies also were conducted using human duodenal bile and animal bile (baboon, dog, and chicken gallbladder bile) for comparison. The dissolution rate resistance, R, ranged from 10^4sec/cm for chicken bile to 10^4-10^6 sec/cm for human bile. Interfacial resistance was the rate-determining factor for all results. Where chemical composition data were obtained, the R values for the human bile samples were consistent with predictions made from the simulated bile studies. In two human gallbladder specimens with low bile acid-lecithin molar ratios (i.e., 2.9 and 2.3), very high R values of 1.9×10^5 and 4.1×10^5 sec/cm were found. These values were in good agreement with the findings in the simulated bile studies and suggest that stone dissolution in patients with low bile acid-lecithin ratios may proceed very slowly, even when the bile is highly undersaturated with respect to cholesterol.

0151 EVALUATION OF A NEW MONKEY MODEL FOR THE REPEATED STUDY OF BILE SECRETORY PHYSIOLOGY.

(Eng.) Wood, R. A. B.; Baker, A. L.; Hall, A. W.; Boyer, J. L.; Moossa, A. R. (Dept. Surgery, Univ. Chicago, 950 E. 59th St., Chicago, IL 60637). *Ann. Surg.* 185(3):349-355; 1977.

An unchaired monkey model for the repeated long-term study of biliary secretory physiology is reported. Postoperative management with cholangiography and long-term follow-up of weight gain and liver function were recorded. Evaluation was performed by repeated measurement, over a period of months, of bile flow and ^{14}C-erythritol clearance at three rates of i.v. taurocholate infusion in a random order. The response to secretin was tested at the final infusion rate of taurocholate for each experiment. The procedure was performed on nine monkeys, two died before the study as a result of surgical complications and two others were studied twice before they died. The remaining monkeys were studied 8, 7, 5, 3, and 2 times, resp., over a 4- to 7-month period. They demonstrated an increase in bile flow and ^{14}C-erythritol clearance with increasing bile salt output. A dramatic choleresis over a wide range of bile salt excretion was noted with secretin, and a linear relationship between bile bicarbonate output and bile salt secretion rate was observed. The new model has several major advantages and gives higher bile flows than previously recorded in the chaired model.

0152 THE CONTRIBUTION OF THE EXTRAHEPATIC BILE DUCTS TO BILE FORMATION.

(Eng.) Strasberg, S. M.; Petrunka, C. N.; Ilson, R. G. (Medical Sciences Bldg., Univ. Toronto, Toronto, Ontario M5S 1A8, Canada). *Can. J. Physiol. Pharmacol.* 54(5):757-763; 1976.

The contribution of the extrahepatic bile ducts to bile flow was examined in the rhesus monkey. Bile flow from the two sides of the liver was divided. The major extrahepatic bile ducts remained connected to only one side of the liver. Bile flow, and the concentration of ^{14}C-erythritol, bicarbonate, bile acid, and bilirubin in bile samples from the two sides of the liver were measured and compared in the fed state. An estimate of the net flow from the extrahepatic ducts was obtained from the ^{14}C-erythritol concentrations on the two sides of the liver and the bile flow rate on the side with the extrahepatic ducts. The ^{14}C-erythritol bile-plasma ratio was significantly lower in bile collected from the side with the extrahepatic bile duct (0.98 ± 0.03) than in bile from the other side of the liver (1.22 ± 0.07, $p<0.05$). About 10% of total hepatic bile flow originated in the extrahepatic bile ducts in the fed state. The bicarbonate ^{14}C-erythritol concentration ratio was significantly higher in bile from the side with the extrahepatic bile ducts ($p<0.05$). Bicarbonate-bile acid, and bicarbonate-bilirubin concentration ratios were also significantly higher in bile from the side of the liver with the extrahepatic ducts. The extrahepatic bile ducts have a physiologically significant role in the secretion of bile water. Bicarbonate is secreted in association with water in the extrahepatic ducts.

0153 THE SYNTHESIS AND EXCRETION OF NONERYTHROID BILIRUBIN IN THE DOG.

(Eng.) Bergan, A.; Ostrem, T.; Enge, I. (Rikshospitalet, Oslo, Norway). *Scand. J. Gastroenterol.* 12(5): 605-609; 1977.

To investigate the synthesis and excretion of nonerythroid bilirubin, sequential samples of arterial, portal, and liver blood, as well as of bile and thoracic duct lymph, were analyzed for bilirubin and nonbilirubin radioactivity following the injection of labeled δ-aminolevulinic acid (^{14}C-ALA, 90-125 µCi, i.v.). After 2 min, only about 15% of the injected radioactivity was found in the plasma. In systemic blood, the first nonerythroid, radioactive bilirubin was detected within 10 min after the injection, and maximum radioactivity was found between 30 and 75 min after precursor injection. In those dogs in which simultaneous liver vein and aortic blood samples were taken, radioactive bilirubin was detected at the same time in the two vascular compartments. The concentration of radioactive bilirubin in the liver vein blood was, however, always lower than that in aortic blood. Lymphatic and bile bilirubin radioactivity was demonstrated at 30 min after the ^{14}C-ALA injection. The fact that the nonerythroid bilirubin is detected in plasma before it appears in the bile excludes enterohepatic circulation. Radioactive bilirubin in the lymph was not only later in appearance than that in the plasma, but also lower in concentration than that in the plasma of dogs with intact biliary passages; these results exclude the possibility that the liver lymphatics are of any importance in the transport of nonerythroid bilirubin from the liver to the blood. Evidence for a direct canalicular excretion of the nonerythroid bilirubin synthesized in the liver was found by comparing the curves for bilirubin and nonbilirubin radioactivity in the lymph and in the bile. In the bile, there was no time lag between nonbilirubin and bilirubin radioactivity. This excludes the possibility that the first bilirubin to appear in the bile is secondary to that in the blood, as was the case for lymph. Like the synthesis of bilirubin in the liver, the process of conjugation is known to be very rapid. These steps should not represent any substantial delay in bilirubin excretion. Thus, nonerythroid bilirubin synthesized in the liver seems to be excreted directly to the bile and does not recirculate through the blood.

0154 ENZYMATIC CONVERSION OF BILIRUBIN MONOGLUCURONIDE TO DIGLUCURONIDE BY RAT LIVER PLASMA MEMBRANES.

(Eng.) Jansen, P. L. M.; Chowdhury, J. R.; Fischberg, E. B.; Arias, I. M. (Albert Einstein Coll. Medicine, Bronx, NY 10461). *J. Biol. Chem.* 252(8):2710-2716; 1977.

The conversion of bilirubin monoglucuronide to bilirubin diglucuronide was studied in subcellular fractions of rat liver. The highest specific activity for bilirubin diglucuronide formation occurred in a fraction highly enriched in plasma membranes. Studies of reaction stoichiometry and utilization of UDP-D-[^{14}C]glucuronic acid revealed that conversion of bilirubin monoglucuronide to bilirubin diglucuronide is not catalyzed by UDP-glucuronyltransferase, and results from transglucuronidation of bilirubin monoglucuronide, with formation of bilirubin diglucuronide and unconjugated bilirubin. When unconjugated bilirubin was infused i.v. into rats at rates exceeding the maximal hepatic excretory capacity, bilirubin monoglucuronide accumulated in serum, and bilirubin diglucuronide was found exclusively in bile as the predominant bilirubin metabolite. These results suggest that the formation of bilirubin diglucuronide occurs at the surface membrane of the liver cell. Conversion of bilirubin monoglucuronide to bilirubin diglucuronide may play a role in the transport of bilirubin glucuronides from liver to bile.

0155 ALTERATIONS PRODUCED IN THE ENDOPLASMIC RETICULUM BY CARBON TETRACHLORIDE. (Eng.)

Smuckler, E. A. (Dept. Pathology, Univ. Washington, Seattle, WA 98195). *Panminerva Med.* 18(9/10):292-309; 1976.

Factors concerning carbon tetrachloride hepatotoxicity are reviewed. The evidence suggests that carbon tetrachloride is metabolized within the hepatocyte. This biochemical modification appears to take place within the endoplasmic reticulum, with a production of proximate toxins that modify cell function and, more specifically, appear to modify the function of the endoplasmic reticulum itself. Both modification of the anabolic function of the membrane and decreased capacity to form proteins, both for cell use and for export, is easily detectable. The injury is associated with a disaggregation of the ribosome-messenger amino acyl-transfer RNA complex, so that essentially "nascent" ribosomes are present. This is not associated with alteration of protein synthesis or with formation of messenger RNA or its transport or lifetime in the cytoplasm. The alteration within the cell sap and within the membrane surface suggests that the active product associated with the change is not localized solely to the endoplasmic reticulum. The modification of the activity of the membranous structure of the endoplasmic reticulum is also not uniform, but rather punctate. This is consistent with the notion that there are "hot spots" that seem to be affected by this toxin and are represented by modifications of these structures and functions. The question of whether the most severe and the most lasting changes are those that appear in the fatally injured cells has not been answered. Although this seems to be true for protein synthesis detected by autoradiography, no simple technique has been provided to carry out a similar study for the membranous components of the endoplasmic reticulum. While it is evident that these modifications are important and potentially meaningful for the maintenance of cellular function, an explanation of their interaction with cellular physiology has not been put forth. Furthermore, it is not known whether this model will provide detailed evidence for mechanisms potentially available and important in the modification of cell structures by other halogenated hydrocarbons.

0156 EARLY ALTERATIONS INDUCED BY CARBON TETRACHLORIDE IN THE LIPIDS OF THE MEMBRANES OF THE ENDOPLASMIC RETICULUM OF THE LIVER CELL: II. DISTRIBUTION OF THE ALTERATIONS IN THE VARIOUS LIPID FRACTIONS. (Eng.)

Benedetti, A.; Casini, A. F.; Ferrali, M.; Comporti, M. (Istituto di Patologia Generale dell'Universita di Siena, Via Laterino 8, 53100 Siena, Italy). *Chem. Biol. Interact.* 17(2):167-183; 1977.

The distribution of the molecular alterations produced by CCl_4 in the various phospholipids of the microsomal membrane was studied to investigate the functional membrane damage caused by the halogenated hydrocarbon. Analysis of various phospholipid moieties showed that phosphatidyl ethanolamine (PE) has the highest diene conjugation absorption, followed by phosphatidyl serine (PS) and phosphatidyl inositol (PI); all show the "D" spot in chromatography. The phosphatidyl choline (PC) fraction contained only a minor absorption of conjugated dienes and no "D" spot. A decrease in arachidonic acid (20:4) content was found in PE ($p<0.05$), while no change in fatty acid pattern occurred in PC or neutral lipids. Quantitative estimation of fatty acid methyl esters of various lipid fractions was done by irreversible binding of ^{14}C from $^{14}CCl_4$ to various lipid classes. PS had the highest specific activity, while PC had the least irreversible binding of CCl_4 free radicals. Thin-layer chromatography of the PS fraction showed that only 11% of the radioactivity was associated with pure PS moiety, while the lipid fraction containing the remaining radioactivity could be an oxidation product. It is suggested that following CCl_4 intoxication, the free radical attack occurring in the PE fraction initiates an intense lipoperoxidation process. In conclusion, the various phospholipid fractions of liver microsomal lipids are affected differently by CCl_4 poisoning.

0157 CARBON TETRACHLORIDE ACTIVATION, LIPID PEROXIDATION, AND THE MIXED FUNCTION OXYGENASE ACTIVITY OF VARIOUS RAT TISSUES. (Eng.)

Villarruel, M. C.; de Toranzo, E. G. D.; Castro, J. A. (Laboratorio de Quimica Bio-Toxicologica, CITEFA, Zufriategui y Varela, Villa Martelli, Pcia. de Buenos Aires, Argentina). *Toxicol. Appl. Pharmacol.* 41(2):337-344; 1977.

Carbon tetrachloride activation, lipid peroxidation, and mixed function oxidase activity were examined in the microsomal fraction of the liver and other tissues from male and female Sprague-Dawley rats. When fasted (12-14 hr) rats were inoculated i.p. with a solution of $^{14}CCl_4$ (27.5 mCi/mmol) in olive oil [14 x 10^6 disintegrations/min (dpm)/ml] in a volume of 5 ml/kg and were then sacrificed 3 hr later, the levels of irreversibly bound ^{14}C to microsomal lipids in male liver, female liver, and pregnant female liver were 1,225 ± 266, 729 ± 78, and 666 ± 330 x 10^3 dpm/g lipid, resp. The corresponding $^{14}CCl_4$ tissue concentrations were 5 ± 1, 5 ± 1, and 8 ± 4 dpm/g tissue, resp. The ratio between the irreversible binding of ^{14}C to microsomal lipids and the free $^{14}CCl_4$ concentration was significantly higher in these liver microsomal fractions than in other tissue microsomal fractions tested, including the kidney. Lipid peroxidation values in microsomal fractions from various tissues 3 hr after fasted rats were given 1 ml/kg of CCl_4 i.p. (expressed as absorbance at 243 nm x 1,000 for a solution containing 1 mg of microsomal lipid/ml) were 285 ± 30, 225 ± 20, and 251 ± 32 for the male liver, female liver, and pregnant female liver, resp., compared to control values of 176 ± 24, 132 ± 10, and 185 ± 42, resp. These differences were statistically significant ($p<0.01$). Lipid peroxidation did not occur after CCl_4 administration in the other tissues tested. There was generally a good correlation between CCl_4 activation in the liver (and other tissues) and cytochrome P-450 content, which measured 0.65 ± 0.23, 0.39 ± 0.06, and 0.09 ± 0.04 nmol/mg protein in the male liver, female liver, and pregnant female liver, resp. No correlation between CCl_4 activation and cytochrome c reductase activity was found. These results suggest that cytochrome P-450 is involved in CCl_4 activation and that irreversible binding of CCl_4 metabolites to cellular components, rather than lipid peroxidation, is responsible for the biochemical and/or ultrastructural tissue lesions due to CCl_4 intoxication.

0158 CIRRHOSIS OF THE LIVER IN RABBITS INDUCED BY A HIGH CHOLESTEROL DIET--AN EXPERIMENTAL MODEL. (Eng.) Gupta, P. P.; Tandon, H. D.; Ramalingaswami, V. (Dept. Veterinary Pathology, Punjab Agricultural Univ., Ludhiana, India). *Indian J. Med. Res.* 64(10):1516-1526; 1976.

Hepatic changes induced in rabbits fed different regimens of high cholesterol diet for a prolonged period of time were studied, and the possible use of these regimens for the study of fatty liver and its evolution into cirrhosis is described. The sequence of changes on continuous cholesterol feeding was: fatty change, which was initially centrilobular, but later became diffuse, with simultaneous accumulation of cholesterol in the parenchymal cells; diffuse portal fibrosis; and eventually "portal" cirrhosis of the monolobular type. Liver cell necrosis seemed to have contributed little to the pathogenesis of cirrhosis. The fibrosis was mainly related to the mesenchymal cell activity in the portal canals. There was no significant regression of changes when cholesterol was withdrawn from the diet after 8 weeks of feeding. One of four animals developed cirrhosis 20 weeks after withdrawal. The precise mechanism of fibrosis and cirrhosis is not understood, but excessive accumulation of cholesterol in the liver probably acts as a cirrhogenic factor. The morphological sequences of the cholesterol-induced portal cirrhosis provide a useful experimental model for the study of the mechanism of cirrhosis, using an endogenous agent, without mediation of nutritional deficiencies.

0159 LIVER DAMAGE FROM COCAINE IN MICE. (Eng.) Shuster, L.; Quimby, F.; Bates, A.; Thompson, M. L. (Tufts Univ. Sch. Medicine, Boston, MA 02111). *Life Sci.* 20(6):1035-1042; 1977.

The effects of cocaine on liver histology, serum transaminase activity, and *in vivo* drug metabolism were studied in mice. Four daily injections of cocaine hydrochloride (20 mg/kg) in B6AF$_1$/J mice produced focal necrosis of liver parenchymal cells in the midzonal region and a fivefold increase in SGOT. Massive liver damage and marked SGOT elevation (from a normal level of 78 ± 8.5 Karmen U [KU]/ml to as high as 25,000 KU/ml) was observed after a single injection of 50 mg/kg cocaine-HCl. This damage led to increased sleep time after pentobarbital, and a decreased rate of pentobarbital metabolism *in vivo*. The results indicate that cocaine is a potent hepatotoxic agent in mice.

0160 UPTAKE AND DEGRADATION OF ^{125}I-LABELLED ASIALO-FETUIN BY ISOLATED RAT HEPATOCYTES. (Eng.) Tolleshaug, H.; Berg, T.; Nilsson, M.; Norum, K. R. (Sch. Medicine, Univ. Oslo, Blindern, Oslo 3, Norway). *Biochim. Biophys. Acta* 499(1): 73-84; 1977.

The uptake and degradation of ^{125}I-labeled asialo-fetuin was studied in isolated rat liver cells, and the distribution of this asialo-fetuin between hepatocytes and nonparenchymal liver cells was examined after i.v. injection. ^{125}I-labeled asialo-fetuin was taken up by a saturable process. Half-maximum uptake was seen at about 3 x 10^{-8} M asialo-fetuin. Nonparenchymal liver cells did not take up asialo-fetuin *in vitro*. The rate of uptake of asialo-fetuin exceeded the rate of degradation at all concentrations of asialo-fetuin tested. Asialo-fetuin consequently accumulated in the cells until the extracellular supply was exhausted. Asialo-fetuin degradation could be studied without concurrent uptake by incubating cells, previously exposed to asialo-fetuin, in asialo-fetuin-free medium. Degradation, as evidenced by increase in acid-soluble radioactivity, was inhibited by NH_4Cl and chloroquine. The change with time in the intracellular distribution pattern of radioactivity in cells that had been exposed to ^{125}I-labeled asialo-fetuin for 10 min was examined by means of differential centrifugation. Initially, the radioactivity was found mostly in the microsomal fraction. One hour after the exposure to labeled protein, the distribution pattern of radioactivity resembled that of the lysosomal enzyme β-acetylglucosaminidase. It is possible that asialo-fetuin digestion takes place in lysosomes.

0161 EFFECT OF DICHLOROACETATE AND GLUCAGON ON THE INCORPORATION OF LABELED SUBSTRATES INTO GLUCOSE AND ON PYRUVATE DEHYDROGENASE IN HEPATOCYTES FROM FED AND STARVED RATS. (Eng.) Claus, T. H.; Pilkis, S. J. (Vanderbilt Univ. Sch. Medicine, Nashville, TN 37232). *Arch. Biochem. Biophys.* 182 (1):52-63; 1977.

The effects of dichloroacetate on the conversion of various labeled substrates into glucose, as well as its effect on pyruvate dehydrogenase activity, were studied in the isolated hepatocytes of fed and fasted rats. Dichloroacetate (2 mM) stimulated the conversion of [1-^{14}C]lactate to glucose in hepatocytes from fed rats. In hepatocytes from rats starved for 24 hr, where the mitochondrial NADH/NAD$^+$ ratio is elevated, dichloroacetate inhibited the conversion of [1-^{14}C]lactate to glucose. Dichloroacetate stimulated $^{14}CO_2$ production from [1-^{14}C]lactate in both cases. It also completely activated pyruvate dehydrogenase and increased flux through the enzyme. The addition of β-hydroxybutyrate, which elevates the intramitochondrial NADH/NAD$^+$ ratio, changed the metabolism of [1-^{14}C]lactate in hepatocytes from fed rats to a pattern similar to that seen in hepatocytes from starved rats. Thus, the effect of dichloroacetate on labeled glucose synthesis from lactate appears to depend on the mitochondrial oxidation-reduction state of the hepatocytes. Glucagon (10 nM) stimulated labeled glucose synthesis from lactate or alanine in hepatocytes from both fed and starved rats and in the absence or presence of dichloroacetate, but the hormone had no effect on pyruvate dehydrogenase activity whether or not the enzyme had been activated by dichloroacetate. It appears, then, that pyruvate dehydrogenase is not involved in the hormonal regulation of gluconeogenesis. Glucagon inhibited the incorporation of 10 mM [1-^{14}C]pyruvate into glucose in hepatocytes from starved rats. Although this inhibition has been previously attributed to an inhibition of pyruvate dehydrogenase by the hormone, dichloroacetate did not prevent the inhibition of glucose synthesis, nor did glucagon alter the activity of pyruvate dehydrogenase in homogenates of cells that had been incubated with 10 mM pyruvate in the absence or presence of dichloroacetate. It is concluded that the inhibition by glucagon of pyruvate gluconeogenesis is not due to an inhibition of pyruvate dehydrogenase.

0162 THE ROLE OF METHIONINE IN GLUTATHIONE BIOSYNTHESIS BY ISOLATED HEPATOCYTES. (Eng.) Reed, D. J.; Orrenius, S. (Dept. Biochemistry and Biophysics, Oregon State Univ., Corvallis, OR 97331). *Biochem. Biophys. Res. Commun.* 77(4): 1257-1264; 1977.

The role of methionine and cysteine in glutathione synthesis was studied in rat hepatocytes after experimental *in vivo* depletion of liver glutathione. Hepatocytes freshly isolated from diethylmaleate (0.6 mmol/kg, i.p.)-treated rats were shown to perform net biosynthesis of intracellular glutathione at approximately an *in vivo* rate. ^{35}S from ^{35}S-cysteine or ^{35}S-methionine each contributed to the formation of glutathione to about the same extent, up to 75% and 61%, resp., depending upon the amino acid concentration in the medium. The sulfur atom of methionine makes a significant contribution to the synthesis of the thiol of glutathione, probably via the formation of cystathionine.

0163 HALOTHANE HEPATOTOXICITY: ENHANCEMENT BY POLYCHLORINATED BIPHENYL PRETREATMENT. (Eng.) Reynolds, E. S.; Moslen, M. T. (Univ. Texas Medical Branch, Galveston, TX 77550). *Anesthesiology* 47(1):19-27; 1977.

Halothane hepatotoxicity was studied in male Sprague-Dawley rats pretreated with polychlorinated biphenyl (Aroclor 1254, 150 µmol/kg, 7 days). Within 2 hr of the end of anesthesia (0.85% for 5 hr), the SGOT and SGPT levels were increased to above normal, and morphologic injury was recognized in the centrilobular parenchymal cells of the pretreated animals. Necrosis of the centrilobular hepatocytes was prominent within 24 hr. The ultrastructure of the hepatic tissue at intervals after anesthesia indicated that the injury primarily involved the endoplasmic reticulum (ER), progressing from dispersion of the rough ER to vacuolization of the rough ER and coalescence of the smooth compenents of this membranous system into tubular aggregates. These changes were preceded by selective deactivation of the mixed-function oxidase components, cytochrome P-450 and zoxazolamine hydroxylase, and early transient increases in conjugated dienes of lipids. Although pretreatment with Aroclor 1254 potentiated halothane hepatotoxicity, neither covalent binding of labeled halothane to liver proteins nor excretion of water-soluble labeled metabolites in the urine was enhanced 24 hr after the i.p. administration of a low nonhepatotoxic or high hepatotoxic dose of ^{14}C-1-labeled halothane (10 and 10,000 µmol/kg, resp.). These findings suggest that the toxic pathway(s) for the biotransformation of halothane do not involve increased production of water-soluble or protein-bound metabolites.

0164 INCREASE OF SERUM VERY LOW DENSITY LIPOPROTEINS IN RATS AFTER ADMINISTRATION OF α-HEXACHLOROCYCLOHEXANE. (Eng.) Grajewski, O.; Oberdisse, E. (Pharmakologisches Institut der Freien Universitat Berlin, Thielallee 69/73, D-1000 Berlin 33, Germany). *Naunyn Schmiedebergs Arch. Pharmacol.* 298(2):129-135; 1977.

The effect of α-hexachlorocyclohexane (α-HCH) on serum lipids and lipoproteins was studied in female Wistar rats. After enteral administration of 200 mg/kg α-HCH the rats developed hyperlipemia. Forty-eight hours after the administration, serum triglycerides were increased by 300%, whereas both serum cholesterol and serum total phospholipids only increased by about 45%. Serum free fatty acids were not significantly altered. Fractionation of the serum lipoproteins by ultracentrifugation showed that the hyperlipemia was due to a fivefold increase in serum very low density lipoproteins. Hepatic triglyceride secretion, calculated after i.v. injection of Triton WR 1339, was increased in animals pretreated with α-HCH. Corresponding to this observation, drugs known to diminish the triglyceride secretion of the liver, such as actinomycin D, cycloheximide, glucagon, orotic acid, CFT 1201, and CFT 1042 reduced the α-HCH-induced hyperlipemia. It is concluded that hyperlipoproteinemia after α-HCH is due to an increased hepatic very low density lipoprotein secretion. Blood sugar level was decreased in fasting animals after α-HCH treatment. Earlier experiments suggest that this effect is due to a decreased gluconeogenesis in the liver.

0165 TOXIC EFFECTS OF INDOCYANINE GREEN ON RAT LIVER MITOCHONDRIA. (Eng.) Laperche, Y.; Oudea, M. C.; Lostanlen, D. (Hopital Henri Mondor, 94010 Creteil, France). *Toxicol. Appl. Pharmacol.* 41(2):377-387; 1977.

Experiments were carried out to determine whether the decrease in bile flow seen in the rat after the administration of indocyanine green (ICG) at rates exceeding the maximal capacity of hepatic transport is dependent on ICG's effects on liver mitochondria. ICG (68-171 nmol/mg protein) inhibited the oxygen consumption of rat liver mitochondria *in vitro*. In state IV respiration, an acceleration of oxygen consumption occurred prior to this inhibition. ICG induced mitochondrial swelling in an isotonic KCl and K^+ acetate medium but not in a 0.27 M sucrose medium. The increase in the ^{42}K diffusion space of isolated mitochondria was significantly larger than that of the ^{14}C sucrose diffusion space, indicating that ICG renders the mitochondrial membrane permeable to K^+ ions. At the same time, an efflux of H^+ ions from mitochondria was observed. The inhibition of mitochondrial oxygen consumption could be the result of a decrease in substrate penetration, as suggested by the diminution in NAD reduction by glutamate or isocitrate in the presence of ICG, without change in the activity of the corresponding dehydrogenases. A nigericin-like-mediated K^+ for H^+ antiport is proposed to account for the effects of ICG upon mitochondrial membrane permeability.

0166 EFFECTS OF ANESTHETIC AGENTS ON THE BILIARY EXCRETION OF IOPANOATE IN THE RAT.

(Eng.) Cooke, W. J.; Cooke, L. (Univ. Massachusetts Medical Sch., 55 Lake Ave. North, Worcester, MA 01605). *Drug Metab. Dispos.* 5(4):377-385; 1977.

The effects of three anesthetics (ether, pentobarbital, and urethane) and decerebration on the metabolism and the biliary excretion following iopanoate administration were compared in Sprague-Dawley rats. Following the administration of ^{125}I-iopanoate glucuronide (13 μmol/kg, i.v.), its biliary excretion was 65% lower in animals anesthetized with ether than in those anesthetized with urethane (800 mg/kg, i.p.); when a high dose of iopanoate (169 μmol/kg) was administered, the difference was less marked but still significant ($p<0.01$). Biliary excretion of iopanoate glucuronide in animals anesthetized with pentobarbital (45 mg/kg, i.p.) was intermediate to that in animals anesthetized with ether and urethane. Decerebrate animals excreted iopanoate glucuronide at rates indistinguishable from those in animals anesthetized with urethane. The variations in biliary excretion of iopanoate glucuronide were accompanied by changes in the plasma decay of iopanoate. The positive relationship between the hepatic and plasma concentrations of iopanoate was unaffected by the anesthetic agent used. Ether significantly decreased the hepatic iopanoate glucuronide/iopanoate ratio, when compared with animals anesthetized with urethane or with decerebrate animals. The relation between the hepatic content of iopanoate glucuronide and the biliary excretion of iopanoate glucuronide was not affected by the anesthetic. The biliary excretory process appears to be saturable with an apparent V_{max} for iopanoate glucuronide of 4 μmol/min/kg and an apparent K_m of 1 μmol/g liver. These data indicate that the hepatic metabolism of iopanoate to iopanoate glucuronide is depressed by ether and by pentobarbital anesthesia in comparison to urethane anesthesia or decerebration.

0167 EFFECT OF ESSENTIAL AND NONESSENTIAL FATTY ACIDS IN COMPLEX MIXTURE ON FATTY ACID COMPOSITION OF LIVER LIPIDS.

(Eng.) Caster, W. O.; Andrews, J. W., Jr.; Mohrhauer, H.; Holman, R. T. (Sch. Home Economics, Univ. Georgia, Athens, GA 30602). *J. Nutr.* 106(12):1809-1816; 1976.

The fatty acid composition of liver lipids was determined and was related to that of diet lipids fed to weanling rats for 60 days. The diet lipids constituted 5% of diet and were fed in the form of 24 different fatty acid ethyl ester mixtures containing 10 major fatty acids proportioned so that the intake of each one was poorly correlated with the intake of the remainder. The correlation coefficient between the amount of fatty acid in the diet and in the liver lipids was close to zero, except for linoleate and docosahexanoate acids (laurate, myristate, oleate). Linoleate fed in lipid mixtures was more effective in raising the concentration in liver lipids than previous studies had shown when the fatty acid was fed alone. The nutritional requirement for linoleate, an essential fatty acid, and the dose-response curve of liver concentration was similar when linoleate was fed in mixtures and alone. It is concluded that each of the polyunsaturated fatty acid components fed in a complex mixture behaves as expected from observations in experiments with diets containing lipids in the form of limited numbers of pure esters.

0168 DIFFERENTIAL EFFECTS OF DIETARY METHYL ESTERS OF LONG-CHAIN SATURATED AND POLYUNSATURATED FATTY ACIDS ON RAT LIVER AND ADIPOSE TISSUE LIPOGENESIS.

(Eng.) Clarke, S. D.; Romsos, D. R.; Leveille, G. A. (Dept. Food Science and Human Nutrition, Michigan State Univ., East Lansing, MI 48824). *J. Nutr.* 107(7):1170-1181; 1977.

Four experiments were conducted to investigate the influence methyl esters of $C_{16:0}$, $C_{18:0}$, $C_{18:1}$, $C_{18:2}$, and $C_{18:3}$ fatty acids exert on rat liver and adipose tissue fatty acid synthesis and related enzymes when supplemented to a fat-free (FF) diet. A randomized complete block design, in which rats were matched for body weight and food intake, was used. Rats previously adapted to a meal-eating regimen (access to food from 0900-1200 hr) were fed a FF diet for 7 days prior to the addition of the respective dietary fatty acids. In experiments 1 to 3, all esters were supplemented at a level of 3% of the daily FF diet allotment. The apparent absorbabilities of $C_{16:0}$ and $C_{18:0}$ were 40% and 35%, resp., while the values for $C_{18:1}$, $C_{18:2}$, and $C_{18:3}$ were 88%, 87%, and 89%, resp. In comparison with the FF dietary treatment, polyunsaturated fatty acids ($C_{18:2}$ and $C_{18:3}$) reduced the rate of hepatic fatty acid synthesis and the activities of hepatic fatty acid synthetase (FAS) and malic enzyme (ME) in three of four experiments. In all four experiments, glucose-6-phosphate dehydrogenase (G6PD) activity was significantly depressed by $C_{18:2}$ and $C_{18:3}$. $C_{18:1}$ produced an intermediate rate of *in vitro* liver fatty acid synthesis, but exerted no significant effect on hepatic lipogenic enzyme activities. Adding $C_{16:0}$ or $C_{18:0}$ to the FF diet had no depressive effect on hepatic fatty acid synthesis, but $C_{18:0}$ supplementation was associated with a significant increase in hepatic FAS, G6PD, and ME activities. Neither unsaturated nor saturated fatty acids affected adipose tissue FAS, G6PD, The lack of influence of $C_{16:0}$ and $C_{18:0}$ may have been partially due to their poor absorbability. Therefore, a level of 7% $C_{16:0}$ supplementation was compared with 3% $C_{18:2}$ or $C_{18:3}$. This resulted in comparable amounts of fatty acid absorbed. Both $C_{18:2}$ and $C_{18:3}$ addition to the FF diet were equally effective in significantly depressing *in vivo* hepatic fatty acid synthesis, and in decreasing FAS, G6PD, and ME activities by more than 50%. $C_{16:0}$ had no suppressive action on liver fatty acid synthesis or related enzyme activities. Adipose tissue lipogenesis remained unchanged by dietary fat treatment. These data demonstrate that $C_{18:2}$ and $C_{18:3}$ specifically inhibit rat liver fatty acid synthesis, independent of carbohydrate intake. Under these conditions adipose tissue lipogenesis was unaffected by low levels of dietary fat, regardless of the degree of unsaturation.

0169 THE EFFECT OF DIETARY LIPID PEROXIDES, STEROLS AND OXIDISED STEROLS ON CYTOCHROME P450 AND OXIDATIVE DEMETHYLATION IN THE ENDOPLASMIC RETICULUM.

(Eng.) Lambert, L.; Wills, E. D. (St. Bartholomew's Hosp., Charterhouse Square, London ECIM 6BQ, England). *Biochem. Pharmacol.* 26(15):1417-1421; 1977.

The effects of dietary linoleate, oxidized linoleate, lipid peroxides, cholesterol, cholesterol hydroperoxides, and squalene on the concentration of cytochrome P450 and rate of oxidative demethylation were examined in the endoplasmic reticulum of the rat liver. Addition of 5% methyl linoleate to a diet containing 5% lard caused a large increase in the rate of oxidative demethylation. Oxidized methyl linoleate (5%) was much less effective and also depressed the rate of oxidation when added to a diet containing corn oil. A supply of dietary linoleic acid or other polyunsaturated fatty acids is essential for maximum rate of oxidative demethylation in the endoplasmic reticulum and for maximum induction by phenobarbitone. Dietary lipid peroxide did not increase the rate of oxidative metabolism in the endoplasmic reticulum or its induction. Feeding a diet that included 10% herring oil and that contained only 1.7% linoleic acid caused a very rapid rate of oxidative demethylation and a high concentration of cytochrome P450 in the liver endoplasmic reticulum. Induction by phenobarbitone was also very effective after feeding this diet. The unsaponifiable fraction of herring oil, added to the lard diet, effectively increased the rate of oxidative demethylation to a value similar to that observed after feeding a diet containing 10% herring oil. The addition of cholesterol (2 g/kg diet) or of squaline (1 g/kg diet) to diets containing 10% lard were less effective than the unsaponifiable fraction of herring oil, but caused a large increase in the content of cytochrome P450 and rate of oxidative demethylation in the endoplasmic reticulum. The induction of phenobarbitone was also enhanced. Cholesterol hydroperoxide was no more effective than cholesterol. A supply of dietary sterols is essential for maximum activity of oxidative demethylation in the liver endoplasmic reticulum, especially when linoleic acid is in restricted supply, and for maximum induction by phenobarbitone. The nonsaponifiable fraction of herring oil cannot be completely replaced in the diet by pure cholesterol, cholesterol hydroperoxide, or squalene.

0170 LIVER AND STEROID HORMONES. II. INFLUENCING THE HEPATIC METABOLISM BY STEROID HORMONES.

(Ger.) Kley, H. K.; Kruskemper, H. L. (2. Medizinische Klinik, Moorenstrasse 5, D-4000 Dusseldorf 1, W. Germany). *Med. Klin.* 72(7): 231-239; 1977.

Studies on relationships between steroid hormones and the liver are reviewed. Cortisol was found to induce the activity of such hepatic enzymes as tryptophan pyrrolase, tyrosine transaminase, pyruvate-glutamate transaminase, pyruvate carboxylase, phosphoenolpyruvate carboxykinase, fructose-1,6-diphosphatase, glucose-6-phosphatase, and glucogen synthetase. No glycogen synthesizing enzymes were found in the liver of adrenalectomized, fasting animals. Twenty percent of patients with Cushing's syndrome have an increased blood glucose level, and 90% show pathological blood sugar load tests. Estrogens increase the hepatic DNA and RNA levels and increase and modify the activity of hepatic enzymes, such as glucose-6-phosphate dehydrogenase and delta-aminolevulinic acid synthetase. Estrogens increase the liver glycogen level, the plasma insulin, total lipid, triglyceride, free fatty acid, cholesterol, and lipoprotein concentrations, and the glycolytic capacity of the liver. The concentrations of practically all specific hormone-binding proteins are increased by estrogens and gestagens, and reduced by androgens. Testosterone increases the activity of fumarate hydratase, transaminase, and delta-amino acid oxidase.

0171 EFFECTS OF CONTRACEPTIVE STEROIDS AND PREGNANCY ON BILE COMPOSITION AND KINETICS IN THE BABOON.

(Eng.) Morrissey, K.; Panveliwalla, D.; McSherry, C.; Deitrick, J.; Niemann, W.; Gupta, G. (New York Hosp.-Cornell Medical Center, New York, NY 10021). *J. Surg. Res.* 22(6):598-604; 1977.

The effect of the contraceptive steroids, ethinylestradiol (EE) and Norethindrone (NET), and of pregnancy on bile acid metabolism was studied in the baboon, an animal that spontaneously forms predominantly cholesterol gallstones as does man. The contraceptive steroids were administered continuously (EE, 65 µg/day; NET, 100 µg/day) via solid Silastic pellets implanted s.c. in the abdomen or sternal region of five baboons (1 male) according to the following protocol: EE, 8 weeks; EE+NET, 10 weeks; NET, 8 weeks. Seven female baboons were used for the pregnancy studies performed prior to and after pregnancy as well as during the second and third trimesters. Gallbladder bile was aspirated percutaneously after a 16-hr fast and on alternate days after i.v. injection of isotopically-labeled bile acids. The response to synthetic sex hormones and to pregnancy was similar: a significant ($p<0.01$-0.05) decrease occurred in biliary cholesterol level and in chenodeoxycholic acid pool size and synthesis rate. When pregnancy had ended or the estrogen component of the contraceptive steroids (EE) was removed, these values reverted to control or antepartum levels. As a result of the concomitant increase in deoxycholic acid pool size, there was no net change in total bile acid pool size during any of the periods of administration of EE or EE+NET, but there was a significant ($p<0.05$) decrease during the third trimester of pregnancy. Over the past 5 yr, a 6% incidence of cholelithiasis among 219 female baboons has been observed, but none occurred in the present study.

0172 INFLUENCE OF DIETARY FAT ON FATTY LIVERS OF CHOLINE-DEFICIENT RATS. (Eng.)

Carroll, C.; Williams, L. (Agricultural Experiment Station, Univ. Arkansas, Fayetteville, AR 72701). *J. Nutr.* 107(7):1263-1268; 1977.

The influence of the type of dietary fat on the nature and severity of liver lipid changes induced by low choline diets was investigated in male weanling rats. Beef tallow, a blend of tallow and safflower oil, or safflower oil (SO) each provided 48% of total energy value of a control diet (0.20 g choline chloride/100 g diet) and a low choline diet (no added choline). Livers from choline-deficient rats fed tallow, blend, or SO diets contained approximately 4.5, 5, and 2.5 times as much lipid, resp., as livers from corresponding control groups. Liver lipids from rats fed SO diets, as compared with those from rats fed tallow diets, contained lower percentages of saturated and mono-unsaturated fatty acids, and higher percentages of polyunsaturated fatty acids. Values for groups fed blend diets were intermediate, except for 18:0 and 20:4 in the control group. Choline deficiency resulted in significant increases in proportions of the predominant fatty acid(s) of the dietary fat in liver lipids (but not in fat pad lipids) at the expense of 18:0 and 20:4. Ratios of 16:0 to 18:0 in both liver and fat pad lipids were greater in choline-deficient rats than in corresponding control groups, probably reflecting greater fatty acid synthesis.

0173 REVERSAL OF OROTIC ACID-INDUCED FATTY LIVER IN RATS BY CLOFIBRATE. (Eng.)

Novikoff, P. M.; Edelstein, D. (Albert Einstein Coll. Medicine, 1300 Morris Park Ave., Bronx, NY 10461). *Lab. Invest.* 36(2):215-231; 1977.

Morphologic observations and biochemical and immunoelectrophoretic results of the reversal of orotic acid-induced fatty liver by clofibrate (CPIB) are presented. The addition of 1% orotic acid to a sucrose-enriched semipurified diet resulted in markedly fatty liver when fed to rats for 7-22 days. Light microscopy revealed lipid droplets distributed throughout the cytoplasm of all hepatocytes. Electron microscopy showed that all the endoplasmic reticulum (ER) was broken into vesicles. Within the interior (cisterna) of each vesicle, one or more lipid droplets were present. Morphologic signs of normal lipid transport (ER to Golgi apparatus to space of Disse) disappeared. The Golgi elements were flattened and lacked very low density lipoprotein particles; the Golgi-derived secretory vacuoles were not present. Biochemical analyses showed an increase in hepatic triacylglycerol levels, to approximately 8 times the levels of sucrose-fed controls by the 7th day, 18 times by the 15th day, and 25 times by the 22nd day. Hepatic cholesterol levels increased two- to fourfold. Serum triacylglycerol levels fell markedly, and serum cholesterol levels were reduced. The apoprotein B component of plasma lipoproteins was practically absent at 7 days and increased slightly at 22 days. By 8-16 days after adding CPIB (0.25%) to the diet, the ER of the hepatocytes returned to its usual parallel configuration, and lipid droplets were not seen within its cisternae. Morphologic features of normal lipid transport reappeared. Lipid-containing residual bodies were common. Peroxisomes were more numerous than in hepatocytes of control rats. Liver triacylglycerol levels approached sucrose-fed control levels, and serum triacylglycerol levels returned to chow-fed control levels. Hepatic cholesterol levels were similar to those of sucrose-fed and chow-fed controls, whereas serum cholesterol levels were lower. Serum apoprotein B levels returned to chow-fed control levels. A sequence of events terminating in the removal of lipid from the hepatocytes is suggested by observation of morphologic changes following CPIB administration.

0174 THE PHARMACOKINETIC PATTERN OF PENTOBARBITAL IN HEPATIC DAMAGE. (Ger.)

Ossenberg, F. W. (I. Med. Abt., Allg. Krankenhaus Barmbek, Rubenkamp 148, 2000 Hamburg 60, W. Germany). *Z. Gastroenterol.* 15(6):393-403; 1977.

The kinetic pattern of distribution and elimination of pentobarbital (PB) was tested in rats with hepatic damage and in 21 patients with liver cirrhosis. After i.v. injection of PB in normal rats, the PB blood level curve showed a dual exponential decreasing course. After total hepatectomy, an initial decrease of PB blood level occurred, corresponding to the distribution of the drug in the body. Thereafter, the PB blood level remained constant, since PB was no longer eliminated due to lack of a liver. Microsomal PB metabolizing liver enzymes and the rate of elimination of PB were reduced in rats after portacaval anastomosis alone or by arterialization of the liver (end-to-end anastomosis between the renal artery and the stump of the portal vein); the cytochrome P450 content of the liver and PB clearance were significantly reduced. Presumably, a hepatotrophic factor in the portal vein blood is necessary for the normal functioning of the hepatic microsomal enzyme system. Rats with extrahepatic cholestasis induced by ligation of the bile ducts had a significantly reduced PB clearance and a decreased initial volume of distribution. PB elimination and initial volume of distribution were significantly reduced in some of the 21 patients with liver cirrhosis; the cause of this disorder has not yet been elucidated. When the rate of PB metabolism is reduced, a delayed action of the drug must be expected. Repeated administration may lead to accumulation in the body.

0175 INDUCTION OF HEPATIC MONO-OXYGENASE SYSTEMS OF PREGNANT RATS WITH PHENOBARBITAL AND 3-METHYLCHOLANTHRENE.

(Eng.) Guenthner, T. M.; Mannering, G. J. (Univ. Minnesota Medical Sch., Minneapolis, MN 55455). *Biochem. Pharmacol.* 26(1): 577-584; 1977.

The selective mechanism governing induction of hepatic mono-oxygenase systems in adult rats during pregnancy was studied. Rats were injected i.p. daily for 4 days with sodium phenobarbital (40 mg/kg in saline), 3-methylcholanthrene (16 mg/kg in corn oil), or progesterone (50 mg/kg in corn oil) in a volume of 2 ml/kg. Ethylmorphine *N*-demethylase, a cytochrome P-450-dependent system, was induced about fourfold in nonpregnant rats but only twofold in pregnant rats when phenobarbital was administered alone. Also the induction of microsomal cytochrome P-450 was about half that observed with nonpregnant rats ($p<0.05$). This impairment of phenobarbital induction occurred within 3 days of conception and disappeared within 5 days after parturition. 3-Methylcholanthrene given alone produced no increase in ethylmorphine metabolism. The depressed response of the maternal liver to phenobarbital induction was partially reversed by the co-administration of 3-methylcholanthrene. The administration of a higher dose (80 mg/kg/day for 4 days) of sodium phenobarbital (PB 80) overcame the pregnancy-related lowered response to phenobarbital induction observed with smaller dose (40 mg/kg/day for 4 days) of the barbiturate (PB 40). Ethylmorphine demethylation in moles HCHO/g/liver/hr was 5.12 ± 0.7 in PB 40 pregnant rats and 11.32 ± 1.2 in PB 80 pregnant rats, which compared to the nonpregnant rats PB 40 value of 11.3 ± 1.4. Progesterone (50 mg/kg) lowered the induction of cytochrome P-450 ($p<0.05$), but induction of mono-oxygenase activity was not lowered. The similarity in responses of the maternal and fetal livers to inducing agents suggests that a common regulatory mechanism operates both in the fetus and in pregnant female rats.

0176 EFFECT OF HYPOPHYSECTOMY ON THE STIMULATION OF LIVER GROWTH BY α-HEXACHLOROCYCLOHEXANE, PHENOBARBITAL, AND PARTIAL HEPATECTOMY IN THE RAT.

(Eng.) Schulte-Hermann, R.; Landgraf, H.; Koransky, W. (Institut fur Toxikologie und Pharmakologie der Philipps-Universitat Marburg, Pilgrimstein 2, D-3550 Marburg a.d. Lahn, W. Germany). *Naunyn Schmiedebergs Arch. Pharmacol.* 298(2):137-142; 1977.

Studies were carried out to determine whether the hypophysis or its hormones are involved in the stimulation of liver cell proliferation elicited by α-hexachlorocyclohexane (α-HCH), phenobarbital (PB), or partial hepatectomy. In hypophysectomized CFHB rats, α-HCH (200 mg/kg, 15-17 days after hypophysectomy and 100 mg/kg 4, 7, and 8 days later) and PB (80 mg/kg on 4 consecutive days from day 18-20 after hypophysectomy and 100 mg/kg on the following 4 days) induced an increase in liver mass, but no increase in liver DNA. Hypophysectomy without additional treatment resulted in a decrease of liver size and RNA, while the DNA content remained unchanged, thereby leading to a relative DNA surplus. One-third hepatectomy in hypophysectomized animals led to a small increase of hepatic DNA only; after two-thirds hepatectomy, 75-80% of the original liver DNA was restored. In rats with an intact hypophysis, losses of liver DNA are known to be restored completely. The findings suggest that the relative DNA surplus in hypophysectomized rats prevents the stimulation of DNA synthesis by weak growth stimuli such as α-HCH, PB, and one-third hepatectomy. If the relative DNA surplus is eliminated by partial hepatectomy, the inducers do produce DNA multiplication. It is concluded that the induction of liver growth and cell multiplication by α-HCH and PB does not require the presence of the hypophysis or one of its hormones.

0177 INDUCTION OF HEPATIC MONO-OXYGENASE SYSTEMS IN FETAL AND NEONATAL RATS WITH PHENOBARBITAL, POLYCLINIC HYDROCARBONS AND OTHER XENOBIOTICS.

(Eng.) Guenthner, T. M.; Mannering, G. J. (Natl. Inst. Child Health and Human Development, NIH, Bethesda, MD 20014). *Biochem. Pharmacol.* 26(7):567-575; 1977.

The hepatic P-450 hemoprotein-dependent mono-oxygenase systems were studied in fetal and neonatal Sprague-Dawley rats born to mothers injected throughout pregnancy with a number of exogenous agents (sodium phenobarbital, 3-methylcholanthrene, dieldrin, chlordane, DDT, 2,4,5-trichlorophenoxyacetic acid [2,4,5-T], α- and β-naphthoflavone, benzo[a]pyrene, dibenz[a,c]anthracene, 3β-hydroxy-20-oxopreg-5-ene-16α-carbonitrile [PCN], and 2-diethylaminoethyl-2,2-diphenylvalerate [SKF 525-A]). Microsomal preparations were made from livers collected on days 13, 16, and 18-22 postconception and 23-25 days postpartum. Phenobarbital (total dose, 80 mg/kg) did not induce the cytochrome P-450-dependent mono-oxygenase activities, aminopyrine or ethylmorphine *N*-demethylase in the fetal liver. Benzo(a)pyrene hydroxylase activity, a cytochrome P$_1$-450-dependent mono-oxygenase activity, was induced in fetal liver by 3-methylcholanthrene (16 mg/kg). All three enzymes were active in neonatal liver. When 3-methylcholanthrene, SKF 525-A, PCN, or dibenz(a,c)-anthracene were administered with phenobarbital, the apparent suppression of phenobarbital-induced mono-oxygenase activities in the fetal liver was partially reversed. The other inducing agents tested were inactive in reversing the suppression. It is concluded that a control mechanism operates in the fetal rat that selectively suppresses induction of cytochrome P-450 but not P$_1$-450 synthesis. Certain pharmacological agents can reverse this suppression.

0178 LONG-TERM STUDIES ON CHEMICALLY INDUCED LIVER ENLARGEMENT IN THE RAT. I. SUSTAINED INDUCTION OF MICROSOMAL ENZYMES WITH ABSENCE OF LIVER DAMAGE ON FEEDING PHENOBARBITONE OR BUTYLATED HYDROXYTOLUENE.

(Eng.) Crampton, R. F.; Gray, T. J. B.; Grasso, P.; Parke, D. V. (British Industrial Biological Res. Assoc., Woodmansterne Rd., Carshalton, Surrey, England). *Toxicology* 7(3):289-306; 1977.

As part of a study on the relationships between liver enlargement, induction of drug metabolizing enzymes, and certain forms of liver damage, sequential biochemical and morphological observations were made on the livers of female Wistar rats fed diets containing 0.4% butylated hydroxytoluene (BHT) or 0.25% phenobarbitone for up to 80 weeks. Both compounds increased the relative liver weight by 35% and 34% with BHT and phenobarbitone, resp., and produced marked enhancement of the activities of ethylmorphine *N*-demethylase, aniline 4-hydroxylase, biphenyl 4-hydroxylase, and NADPH-cytochrome c reductase and of the contents of cytochromes P-450 and b_5 and microsomal protein (by 95%, 15%, 91%, 32%, 83%, 78%, and 50%, resp.). These changes were evident after 1 week of treatment and persisted until treatment was stopped after 80 weeks. The only morphological changes observed throughout the treatment period were centrilobular cell enlargement and hypertrophy of the smooth endoplasmic reticulum. Histochemical examination revealed a centrilobular depression of glucose-6-phosphatase, but there was no disturbance of the normal pericanalicular distribution of lysosomes. All changes observed with either compound were reversible on cessation of treatment at week 80. These results support the concept that liver enlargement accompanied by induction of drug metabolizing enzymes represents an adaptive response, and they provide a basis for the interpretation of pathological changes developing in the enlarged liver unaccompanied by drug metabolizing enzyme induction.

0179 LONG-TERM STUDIES ON CHEMICALLY INDUCED LIVER ENLARGEMENT IN THE RAT. II. TRANSIENT INDUCTION OF MICROSOMAL ENZYMES LEADING TO LIVER DAMAGE AND NODULAR HYPERPLASIA PRODUCED BY SAFROLE AND PONCEAU MX.

(Eng.) Crampton, R. F.; Gray, T. J. B.; Grasso, P.; Parke, D. V. (British Industrial Biological Res. Assoc., Woodmansterne Rd., Carshalton, Surrey, England). *Toxicology* 7(3):307-326; 1977.

A long-term study with Safrole and Ponceau MX was carried out in female Wistar rats to determine whether changes in hepatic drug metabolizing enzyme activity are correlated with the development of liver injury. Sequential biochemical and morphological observations were made on the livers of rats fed a diet containing 0.25% safrole or 1.0% Ponceau MX for up to 85 weeks. After the administration of safrole for 7 days, the relative liver weight was increased by 20% above the control value, and the activity of the drug metabolizing enzymes was enhanced by 75-210%. This enzyme induction was short-lived, however, and continued administration of safrole led to inhibition of drug metabolizing activity. Despite this, the liver remained enlarged, and concentrations of NADPH-cytochrome c reductase, cytochrome b_5, and microsomal protein were markedly elevated. During the initial phase of enzyme induction, no histochemical or morphological abnormalities were evident, but the loss of this inductive response was associated with histochemical and ultrastructural evidence of liver damage. The enlarged liver produced by Ponceau MX was initially accompanied by moderate induction of the drug metabolizing enzymes, followed by a gradual reversal as treatment continued. Histochemical evidence of liver damage was encountered after only 1 week of treatment. The early cytological changes produced by both compounds were followed by the development of fatty change, cell necrosis and, ultimately, hepatic nodules. Liver enlargement unaccompanied by induction of the drug metabolizing enzymes may provide an early index of hepatotoxicity.

0180 SYNTHESIS OF GLYCOPROTEINS IN THE GOLGI COMPLEX OF THE MOUSE GALLBLADDER EPITHELIUM DURING FASTING, REFEEDING, AND GALLSTONE FORMATION: A LIGHT MICROSCOPIC AUTORADIOGRAPHIC AND QUANTITATIVE ELECTRON MICROSCOPIC STUDY.

(Eng.) Wahlin, T. (Dept. Histology and Pathology, Univ. Umea, S-901 87 Umea, Sweden). *Histochemistry* 51(2/3): 133-140; 1977.

The mouse gallbladder epithelium was studied during fasting, refeeding, and experimental gallstone formation to establish if quantitative and qualitative variations in food intake in mice are reflected in the incorporation pattern of radioisotope into epithelial cell glycoproteins and in morphological changes at the site of glycoprotein synthesis, i.e., in the Golgi complexes of the gallbladder principal cells. Control gallbladder epithelium, examined after an intraperitoneal injection of $[^3H]$galactose (0.1 mCi) showed labeling of the supranuclear Golgi region in all normal principal cells at 10 min and an increased radioactivity throughout the apical cytoplasm at 25 min. At 40 min, after $[^3H]$galactose injection, silver grains were mainly present at the cell surface. Autoradiographs processed 25 min after $[^3H]$galactose injection that followed a 48-hr fast showed decreased supranuclear and apical radioactivity. After refeeding (12 hr), there was an enhanced activity in both these regions, roughly equal to the activity observed in controls. Animals fed a lithogenic diet for one month showed a marked increase of radioactivity, mainly in cells of crypts and invaginations of the gallbladder mucosa. Morphometric measurements of the Golgi apparatus revealed that deprivation of food reduced to 2.7% ($p<0.01$) and refeeding restored (to 4.2%, $p<0.05$) the volume density of the Golgi apparatus. In the course of gallstone formation there was a further increase to 6.4% ($p<0.001$) in the volume density of the Golgi complexes as compared to that in controls (4.4%). It is concluded that the synthesis of glycoproteins in the mouse gallbladder principal cells is dependent both on the nutritional state of the mice and the qualitative composition of the diet given to the animals.

0181 ENDOGENOUS INHIBITORS OF PROTEIN SYNTHESIS IN ISCHAEMIC LIVERS. (Eng.) Bernelli-Zazzera, A. (Istituto Patologia Generale, Via Mangiagalli 31, 30133 Milano, Italy). *Panminerva Med.* 18(9/10):326-331; 1976.

Factors leading to the conclusion that the inhibition in protein synthesis seen in the ischemic liver is due to endogenous inhibition are reviewed. The interruption of the blood supply impairs protein synthesis in various cellular or cell-free preparations from ischemic livers (tissue slices, post-mitochondrial supernatants, microsomes, isolated polysomes, cell sap). This inhibition depends on the decay of many metabolic reactions and structures involved in the pathway of protein synthesis. Ribosomal RNA decreases; polysomes break down; there is an actual drop in the number of active particles, rather than a proportional loss of functional capacity of all the ribosomes; and ribosome-membrane relationships become looser. In the cell sap, the activity of both synthetases and transferases is reduced. In ischemic cells, the energy to drive the reaction of protein synthesis is drastically lowered, due to mitochondrial damage. Initiation of new peptides seems to be mainly inhibited, but there is also evidence of impairment of elongation of the initiated chains. At least some of the changes in protein synthesis are related to the increase in concentration of endogenous metabolites, such as ADP, AMP, NADH, and other unidentified molecules accumulating in ischemic liver cells, and possibly to changes in the ratios that describe the "energy state" and the "redox state" of the liver cell.

0182 COMPARATIVE STUDY OF PROTOPORPHYRINS IN ERYTHROPOIETIC PROTOPORPHYRIA AND GRISEOFULVIN-INDUCED MURINE PROTOPORPHYRIA. BINDING AFFINITIES, DISTRIBUTION, AND FLUORESCENCE SPECTRA IN VARIOUS BLOOD FRACTIONS. (Eng.) Poh-Fitzpatrick, M. B.; Lamola, A. A.; Zalar, G. L.; Weinstein, M.; Doleiden, F.; Freeman, M. (Columbia Univ. Coll. Physicians and Surgeons, New York, NY 10032). *J. Clin. Invest.* 60(2):380-389; 1977.

The use of griseofulvin-induced murine protoporphyria (GFPP) as a model for erythropoietic protoporphyria (EPP) and the use of tissue localization of protoporphyrin(s) (PP) as a criterion for the tissue source of PP were assessed in Sprague-Dawley mice. Stroma from GFPP mice and EPP patients contained only a small fraction (0.5%) of the total RBC PP. Thus, 99.5% of the PP was associated with the cytosol hemoglobin (Hb) in both cases. The close agreement in PP distribution among the plasma, stroma, and Hb pools failed to help define any difference in sites of PP overproduction in GFPP and EPP. However, as shown by fractionation of RBC into populations of progressive age on discontinuous density gradients, PP distributions among RBC of different ages are diametrically opposed in GFPP and EPP. The murine RBC became more PP-laden with age in circulation, but there was a rapid loss of PP with age in EPP. Direct competition experiments showed that PP binds about 40 times more strongly to human Hb than it does to human serum albumin (HSA). The molar ratio of Hb to HSA is about 6:1. Assuming that all other plasma sites contribute to PP binding as importantly as HSA, the ratio of PP bound to Hb:PP bound to plasma proteins at equilibrium can be expected to be at least 120:1. This strong affinity can provide the driving force necessary for the net diffusion of PP from the plasma to the intracellular Hb in GFPP mice and it can explain the buildup of the high RBC PP levels. The opposite rapid efflux of intra-RBC PP into plasma occurs despite this strong Hb affinity, implying continuous, efficient clearance of PP from the plasma by the liver. These and other data suggest that liver-formed PP cannot significantly contribute to the circulating PP pool.

0183 THE HEPATIC HANDLING OF ^{131}I-LABELED SULFOBROMOPHTHALEIN IN THE DOG. COMPARISON WITH SULFOBROMOPHTHALEIN. (Eng.) Glasinovic, J. C.; Delage, Y.; Erlinger, S. (Hopital Beaujon, 100, Boulevard du General Leclerc, 92110 Clichy, France). *Biomedicine [Express]* 25(7):255-258; 1976.

The influence of added radioiodine on the hepatic extraction and biliary excretion of BSP was studied in dogs. Two types of experiments were performed. In the first, a compartmental analysis of BSP and ^{131}I-labeled BSP disappearance curves was performed after the simultaneous injection of BSP (5 mg/kg) and ^{131}I-labeled BSP (10 μCi). Both the plasma to liver and liver to bile transfer rates were significantly lower for ^{131}I-labeled BSP than for BSP; the liver to plasma transfer rates were not significantly different. In the second series of experiments, the hepatic uptake of BSP and ^{131}I-labeled BSP was estimated by the multiple indicator dilution technique. The extraction of BSP (59 ± 5%) was significantly higher than that of ^{131}I-labeled BSP (35 ± 5%, $p<0.001$). The labeling of BSP with ^{131}I significantly modifies the hepatic handling of the dye; ^{131}I-labeled BSP thus cannot be used as a tracer of BSP.

0184 HEPATIC UPTAKE AND BILIARY EXCRETION OF DIBROMOSULPHTHALEIN. ALBUMIN DEPENDENCE, INFLUENCE OF PHENOBARBITAL AND NAFENOPIN PRETREATMENT AND THE ROLE OF Y AND Z PROTEIN. (Eng.) Meijer, D. K. F.; Vonk, R. J.; Keulemans, K.; Weitering, J. G. (Bloemsingel 1, Groningen, Netherlands). *J. Pharmacol. Exp. Ther.* 202(1): 8-21; 1977.

The hepatic uptake and biliary excretion of 3,6-bromphenolphthalein-disulfonate (DBSP) in perfusion studies was compared with *in vivo* DBSP kinetics, and an attempt was made to establish a possible role of Y (ligandin) and Z proteins in the hepatic uptake, storage, and excretion of this anion. The uptake and excretion of DBSP was studied in isolated perfused rat livers from control rats and from rats pretreated with phenobarbital (90 mg/kg, for 6 days) or with nafenopin (200 mg/kg, for 2 days). The flow rates of perfusate in control and treated groups were kept equal. Hepatic content of Y and Z proteins was determined by dye binding using gel filtration. DBSP was found to be associated with both Y and Z proteins in liver cytosol. DBSP clearance was studied using various concentrations of bovine albumin in the perfusion medium. Clearance was monoexponential with 3.0% albumin and under this condition mainly reflects biliary excretion of DBSP. At concentrations of 1.0%, 0.5%, and 0.2% albumin, a distinct biexponential plasma disappearance curve was found, from which rate constants for transfer from plasma to liver (K_{12}), liver to plasma (K_{21}), and liver to bile (K_{23}) were calculated. K_{12} was enhanced and K_{21} was lowered with decreasing albumin concentrations, whereas K_{23} was not affected. Phenobarbital treatment increased Y protein concentration twofold and left Z protein unchanged; nafenopin pretreatment slightly elevated Y protein and increased Z protein concentration threefold. With perfusate with 1% albumin, K_{12} was unchanged and K_{23} was increased in the phenobarbital experiments, whereas K_{21} was reduced. In the livers from nafenopin-pretreated rats, K_{21} was reduced and K_{12} and K_{23} were unchanged. Data on binding of DBSP at various albumin concentrations indicate that primary hepatic uptake (K_{12}) and reflux (K_{21}) both are influenced by variations in plasma albumin concentration but are not directly related to the free drug concentration. Phenobarbital pretreatment does not lead to an acceleration of primary hepatic uptake, a result possibly related to the flow-standardized condition compared with the *in vivo* situation. Induction of Y and Z proteins possibly contributes to the lower reflux of DBSP from liver into plasma, an effect that was also observed in the rat *in vivo*.

0185 CHANGES IN RENAL FUNCTION AND WATER-SALT METABOLISM IN RATS DURING INDUCTION OF TOXIC LIVER CIRRHOSIS. (Rus.) Gapon, L. I. (Chernovtsy Medical Inst., Chernovtsy, USSR). *Patol. Fiziol. Eksp. Ter.* (3):82-84; 1977.

0186 PECULIARITIES ASSOCIATED WITH THE DEVELOPMENT OF EXPERIMENTAL HEPATOCHOLECYSTITIS IN SUCKLING RABBITS. (Rus.) Tarakhovsky, M. L.; Lukyanova, E. M.; Emaikina, V. P.; Denisova, M. F.; Oleshko, L. SECRETION AND METABOLISM

Intestine

0215 THE ORIGIN OF CHYLOMICRON PHOSPHATIDYLCHOLINE IN THE RAT. (Eng.) Mansbach, C. M., II. (Veterans Admin. Hosp., Durham, NC 27710). *J. Clin. Invest.* 60(2):411-420; 1977.

Two pathways of origin of chylomicron phosphatidylcholine (CM PC), *de novo* synthesis and lyso PC-derived PC, were investigated using lymph and bile fistulated Sprague-Dawley rats infused with a stabilized triolein emulsion. To quantitate the contribution of PC generated by lyso PC acyltransferase to CM PC, [^{14}C-glycerol]PC was infused into the duodenum. The percentage of CM PC increased as the concentration of PC was increased in the infusate. Over 4-6 hr, virtually all the CM PC was derived from the PC infused when the infusate PC concentration was 10 mM. None of the infused [^{14}C-glycerol]PC was found in the aqueous phase of the gut luminal contents; i.e., there is minimal liberation of free PC glycerol within the intestinal lumen. There was less incorporation of radiolabel in the lymph subnatant PC, suggesting that CM and lymph subnatant PC are derived from different PC precursor pools. To determine the amount of CM PC synthesized from *de novo* sources, similarly prepared rats were infused with $^{32}P_i$. $^{32}P_i$ incorporation was used to represent *de novo* PC synthesis ultimately via the choline-dependent pathway. As the infusate PC concentration was increased, progressively less CM PC was derived from the infused $^{32}P_i$. Thus, exogenously infused PC inhibits *de novo* PC synthesis. When [^{32}P]bile PC and [^{14}C]-potato PC were infused into rats, the ratio of bile to potato derived PC in the CM averaged 1.72; i.e., bile PC was preferred as a CM PC precursor despite the greater similarity of the saturated fatty acids of potato PC to those of CM PC. The predominant saturated fatty acid of bile PC is palmitite, but palmitate and stearate are nearly equally present in CM PC, suggesting that the former cannot be the preferred precursor of the latter. The results suggest that PC synthesized from either pathway is preferentially distributed into the CM PC precursor pool, compared to the subnatant pool, and that these two pools are different.

0216 STEROL SYNTHESIS IN INTESTINAL VILLI AND CRYPT CELLS OF RATS AND GUINEA PIGS. (Eng.) Muroya, H.; Sodhi, H. S.; Gould, R. G. (Kyoto Univ. Faculty Medicine, Sakyo-ku, Kyoto, Japan). *J. Lipid Res.* 18(3):301-308; 1977.

The role of guinea pig and rat small intestinal villi and/or crypt cells in sterol synthesis was investigated. Three methods were used to measure sterol synthesis: incubation with ^{14}C-acetate of villi, crypt cell, and muscle fractions obtained by the method of graduated scraping, incubation of whole intestine pieces followed by fractionation into the same fractions, and *in vivo* studies in rats injected with ^{14}C-acetate and killed 7-40 min later, after which the intestine was fractionated by scraping or by serial sectioning of frozen tissue. All methods were in agreement in showing sterol synthesis in villi to be as active per mg protein as in crypt cells. Measurements of the isotope content of the total nonsaponifiable lipid fractions led to the same conclusions as did the isotope content of the digitonin-precipitable sterol fractions. For a given period of incubation, the ratio of the two values was the same in villi and crypts, ruling out the possibility of synthesis of sterols in crypts prior to transfer to villi. The fractionation into villi, crypts, and muscle fractions by scraping greatly reduced the total sterol synthetic activity in rat but not in guinea pig small intestine, indicating the hazard of using only this *in vitro* technique to make quantitative estimates of the sterol synthetic capacity of tissue fractions.

0217 EFFECT OF SMALL BOWEL RESECTION ON GASTRIN RELEASE, CATABOLISM, AND ACTIVITY IN DOGS.

(Eng.) Woussen-Colle, M. C.; Brihaye, Cl.; Limbosch, J. M.; De Graef, J. (Hopital Universitaire Saint-Pierre, Rue Haute, 322, B. 1000 Brussels, Belgium). *J. Surg. Res.* 21(4):225-232; 1976.

The effects of upper small bowel resection on the catabolism and activity of gastrin were determined in three dogs prepared with a vagally denervated Heidenhain pouch (HP) and a gastric fistula (GF). Conditions prior to testing varied: starvation, feeding, and infusion of exogenous gastrin. All tests were made before and 1 and 6 months post-resection (PR) of the upper half of the small bowel starting 10 cm from the ligament of Treitz. Continuity was restored by a two-layer end-to-end bowel anastomosis. At 1 month PR, peak acid output over 30 min from the HP was (in mEq, pre-resection values in parentheses): 2.17 ± 0.26 (1.73 ± 0.30), $p<0.05$, in response to exogenous gastrin and 3.62 ± 0.25 (2.20 ± 0.44), $p<0.01$, in response to feeding. The total acid output over 5.5 hr was 29.38 ± 1.67 (12.72 ± 2.41), $p< 0.01$. At 6 months PR, the respective values were 1.89 ± 0.26 ($p>0.05$), 2.62 ± 0.35 ($p>0.05$), and 22.23 ± 3.12 ($p<0.01$). At 1 month PR, immunoreactive serum gastrin levels were 131.7 ± 28.3 pg/ml (41.8 ± 4.0), $p<0.01$; peak gastrin concentration after feeding was 478.3 ± 47.0 pg/ml (144.1 ± 25.0), $p<0.01$, and the integrated gastrin response after feeding was 59.3 ng/ml/5 hr (11.4 ± 2.2), $p<0.01$. At 6 months PR, these values were 65.9 ± 3.7 pg/ml ($p<0.01$), 227.3 ± 33.2 ($p<0.05$), and 24.7 ± 4.0 ng/ml/5 hr ($p<0.01$). The metabolic clearance rate of exogenous gastrin before resection and 1 and 6 months PR was 95.2 ± 11.9, 68.6 ± 8.8 ($p<0.05$), and 107.5 ± 11.2 ($p>0.05$) ml/kg/min, resp. The increased acid response from the HP to a meal PR is due to increased reactivity and increased stimulation of the parietal cells. These effects could be related to the removal of intestinal inhibitors acting on parietal and G cells and/or to the interruption of inhibitory neural reflexes between the small bowel and stomach. In dogs, the small bowel appears to control gastric secretion and gastrin release by humoral and/or neural mechanisms. PR, the mechanism is impaired, but a progressive adaptation takes place, partly as a result of hyperplasia (in the remaining small bowel) of cells catabolizing gastrin and those secreting enterogastrones.

0218 THE INTESTINAL BRUSH BORDER MEMBRANE IN DIABETES: STUDIES OF SUCRASE-ISOMALTASE METABOLISM IN RATS WITH STREPTOZOTOCIN DIABETES.

(Eng.) Olsen, W. A.; Korsmo, H. (William S. Middleton Memorial Veterans Admin. Hosp., Madison, WI 53706). *J. Clin. Invest.* 60(1):181-188; 1977.

To determine the mechanism by which diabetes stimulates the functional activity of the intestinal brush border membrane, the effects of streptozotocin diabetes on the metabolism of one membrane protein, sucrase-isomaltase, was studied in male Sprague-Dawley rats. The protein was purified, and an anti-serum was prepared. Sucrase-isomaltase from control and diabetic rats was immunologically identical as shown by Ouchterlony double-diffusion analysis of papain-solubilized mucosal proteins. The increase in sucrase enzyme activity in diabetic animals (31.0 ± 1.4 U 5 days after streptozotocin versus 13.1 ± 1.0 in controls) was the consequence of increased enzyme protein and was not an alteration in catalytic efficiency, as demonstrated by quantitative immunoprecipitin reactions. To account for increased sucrase-isomaltase protein in diabetes, papain-solubilized mucosal proteins labeled by injection of ^{14}C-carbonate and ^{14}C-leucine were studied. Diabetes did not affect the decay of labeled total protein, but prolonged the decay of labeled sucrase-isomaltase. The half time of sucrase-isomaltase was 4.4 hr in control animals after ^{14}C-carbonate injection and 8.8 and 10.2 hr 2 and 5 days, resp., after induction of streptozotocin diabetes. Similar results were obtained in experiments with ^{14}C-leucine with diabetes increasing the half-time from 6 to 13.6 hr. Diabetes did not appear to increase the rate of addition of sucrase-isomaltase to the brush border membrane, since it did not affect the 10- and 60-min incorporations of isotope into sucrase-isomaltase protein relative to incorporation into total protein and did not alter rate constants for synthesis calculated from the half-time and the change in enzyme mass over time. Thus, enhanced sucrase activity in the diabetic animal is the consequence of an increase in sucrase-isomaltase protein, which develops because of a decrease in its rate of degradation.

0219 SOME OBSERVATIONS ON THE DETERMINATION OF EXTRACELLULAR FLUID VOLUME OF JEJUNAL TISSUE USING [^{3}H]INULIN AND [^{14}C]INULIN.

(Eng.) Dinda, P. K.; Beck, I. T.; Beck, M. (Hotel Dieu Hosp., Kingston, Ontario, Canada). *Can. J. Physiol. Pharmacol.* 55(3):389-393; 1977.

The nature of equilibration of [^{3}H]inulin and [^{14}C]-inulin was examined in the *in vitro* hamster jejunum. Rings of everted jejunum were incubated at 37 C in Krebs-Ringer bicarbonate solution containing 10 mM glucose, tracer amounts of [^{14}C]inulin, and tracer amounts of [^{3}H]inulin from one of the two lots (lot X and lot Y) tested. The incubations were carried out for 5, 10, 20, 30, 45, or 60 min. One lot of [^{3}H]inulin (lot X) provided an estimate of the extracellular (EC) fluid volume which, at all periods of incubation, was comparable with that provided by the [^{14}C]inulin. In contrast, the estimate of EC fluid volume obtained from the other lot of [^{3}H]-inulin (lot Y) was consistently higher than that obtained from the [^{14}C]inulin and increased linearly with the period of incubation. Because, with [^{3}H]-inulin of lot Y, the calculated intracellular (IC) fluid volume decreased linearly with the period of incubation, and because this was not the case with the [^{14}C]inulin or with the [^{3}H]inulin of lot X, it appears that [^{3}H]inulin of lot Y failed to equilibrate within the tissue water, while the other lot of [^{3}H]inulin (lot X), as well as [^{14}C]-inulin, did. Although the EC fluid volume obtained from [^{14}C]inulin (as well as that from [^{3}H]-inulin of lot X) increased progressively, the rate of increase during the first 30 min was considerably higher than that during the last 30 min of incubation. The progressive increase in the $[^{14}C]$-inulin space, however, was accompanied by a corresponding increase in the total water content as well as in the calculated IC fluid content of the tissue. Since the IC fluid volume as percentage of total water content after 5 min of incubation was not significantly different from that after 60 min of incubation, it appears that $[^{14}C]$inulin equilibrates within the EC fluid after 5 min, and that the progressive increase in the calculated EC fluid volume is the result of a corresponding increase in the EC fluid (containing $[^{14}C]$inulin) content of the tissue.

0220 DIFFERENTIATION OF EPITHELIAL CELLS IN HUMAN JEJUNUM: LOCALIZATION AND QUANTIFICATION OF AMINOPEPTIDASE, ALKALINE PHOSPHATASE AND ALDOLASE ISOZYMES IN TISSUE SECTIONS.

(Eng.) Wachsmuth, E. D. (Friedrich Miescher-Institut, P.O. Box 273, CH-4002 Basel, Switzerland). *Histochemistry* 48(2):101-109; 1976.

Aminopeptidase, alkaline phosphatase, and aldolase isozyme activities were studied in human jejunal crypt cells at different stages of differentiation. Jejunal sections were stained histochemically for aminopeptidase and alkaline phosphatase, and the aldolase isozymes were detected with the mixed aggregation immunocytochemical technique. All enzyme concentrations increased from the bottom to the upper part of the crypt. The concentration of aldolase-A per cell was the same in the upper part of the crypt and the villus, whereas the concentration of the other three enzymes was still higher. Therefore, high amounts of aldolase-B, aminopeptidase, and alkaline phosphatase are present in cells highly active in absorption in a fashion similar to that found in the proximal tubule cells of kidney. The relatively undifferentiated cells of the crypts contained both aldolase-A and aldolase-B. Alkaline phosphatase gains its full activity later than aminopeptidase. The synthesis of microvillar membrane enzymes comes to an end earlier than that of the cytosol enzymes.

0221 HCO_3^- AN H^+ SECRETION IN RAT ILEUM IN VIVO.

(Eng.) Podesta, R. B.; Mettrick, D. F. (Dept. Zoology, Univ. Toronto, Ontario M5S 1A1, Canada). *Am. J. Physiol.* 232(6):E574-E579; 1977.

Ion transport was studied in the *in vivo* rat ileum. Replacing Cl^- in the perfusion fluids decreased the luminal pH of perfused ileum. Varying the initial pH in Cl^--depletion studies indicated an equilibrium pH near 6.6. Na^+ depletion in Cl^--depleted fluids partially inhibited luminal acidification. Addition of HCO_3^- accelerated Na^+ absorption and decreased Cl^- absorption. Luminal PCO_2 was increased using fluids buffered to initial pH 6.6, suggesting secretion of HCO_3^- rather than OH^-. The decreased HCO_3^- secretion using Cl^--depleted fluids was not due to an accelerated rate of H^+ secretion. Reaffirmed and expanded in this study is an ileal H^+ secretory process that is partially related to Na^+ absorption and direct HCO_3^- secretion that is related to Cl^- and Na^+ absorption.

0222 Ca IONOPHORE-STIMULATED ION SECRETION IN RABBIT ILEAL MUCOSA: RELATION TO ACTIONS OF CYCLIC 3',5'-AMP AND CARBAMYLCHOLINE.

(Eng.) Bolton, J. E.; Field, M. (Beth Israel Hosp., Boston, MA 02215). *J. Membr. Biol.* 35(2):159-173; 1977.

The possibility that calcium acts as a mediator of secretion in the small intestine was investigated, and experiments were carried out to determine whether cholinergic agonists or serotonin act as calcium ionophores. Addition of the Ca ionophore A23187 (0.5 μg/ml) to the serosal side of stripped rabbit ileal mucosa produced changes in ion transport qualitatively identical with those produced by cyclic 3',5'-AMP (cAMP) and theophylline: an increase in short-circuit current and resistance, net secretion of Cl due both to a decrease in the unidirectional mucosa (*m*) to serosa (*s*) flux and to an increase in the *s* to *m* flux, and net secretion of Na due to a decrease in *m* to *s* flux. Measurements of intracellular cAMP level demonstrated no change following incubation with the ionophore. Removal of Ca from the serosal bathing medium diminished the effects of A23187 but did not impair the action of theophylline. Removal of Ca from both the mucosal and serosal bathing media by replacing it with Sr completely abolished the potential difference response to A23187. These results suggest that the ionophore elicits its secretory actions by decreasing Ca influx into the epithelial cells. In a similar way, carbamylcholine and serotonin, secretagogues known to have no effect on intracellular cAMP level in intestinal mucosa, were shown to be dependent on extracellular Ca to produce their full electrical response. In contrast, the secretagogues vasoactive intestinal peptide and prostaglandin E_1, which raise cAMP concentration in intestinal mucosa, do not appear to require external Ca. Ca may be an intracellular mediator of intestinal ion and water secretion, and some intestinal secretagogues may act as Ca ionophores.

0223 ISOLATION AND IMMUNOCHEMICAL AND CHEMICAL CHARACTERIZATION OF CARCINOEMBRYONIC ANTIGEN-LIKE SUBSTANCES IN COLON LAVAGES OF HEALTHY INDIVIDUALS.

(Eng.) Egan, M. L.; Pritchard, D. G.; Todd, C. W.; Go, V. L. W. (Dept. Microbiology, Univ. Alabama in Birmingham, University Station, Birmingham, AL 35294). *Cancer Res.* 37(8):2638-2643; 1977.

Material with carcinoembryonic antigen (CEA)-like activity, isolated from colon lavages of healthy individuals, was chemically characterized. The CEA-like activity was purified by gel filtration on Sepharose 6B and Sephadex G-200 and by affinity chromatography on concanavalin A linked to Sepharose. The purified material migrated in polyacrylamide-sodium dodecyl sulfate electrophoresis as a single diffuse band with mobility identical with that of tumor CEA. The material with CEA activity from tumor tissue and from normal colon lavages gave lines of identity in double diffusion experiments and had similar inhibition curves with essentially the same specific activities in a radioimmune assay for tumor CEA. The amino acid and carbohydrate compositions were similar to that observed for CEA tumor preparations. Lysine was the single amino terminus. Methylation analysis demonstrated that the monosaccharide linkages were similar to those in CEA isolated from tumor tissue. The data support the view that CEA is not restricted to fetal and neoplastic tissue but is also present in healthy adult tissue.

0224 FUNCTIONAL AND MORPHOLOGICAL STUDIES ON INTESTINAL MUCOSA OF THE RAT UNDER CHRONIC GLUCAGON APPLICATION. (Ger.) Lorenz-Meyer, H.; Menge, H.; Riecken, E. O. (Medizinische Universitatsklinik, Mannkopffstrasse 1, D-3550 Marburg/Lahn, W. Germany). *Res. Exp. Med.* 170(2):181-192; 1977.

GENERAL

0231 ULTRASTRUCTURAL CHANGES IN THE GASTRIC MUCOSA FOLLOWING HEMORRHAGIC SHOCK IN PIGS. (Eng.) Collan, Y.; Kivilaakso, E.; Kalima, T. V.; Lempinen, M. (Second Dept. Pathology, Univ. Helsinki, Helsinki, Finland). *Circ. Shock* 4(1):13-25; 1977.

Ultrastructural changes in the gastric mucosa of 14 piglets subjected to transient hemorrhagic shock (3-hr duration, mean arterial pressure 40 mm Hg) were studied. After 30 min, there was mucosal edema and extravasation of RBC. Microthrombi with degranulating thrombocytes and fibrin strands were seen in the capillaries. These changes were also seen in the antral mucosa. At this stage the cells of the neck region of the gastric glands showed mitochondrial dilatation, and their apical parts were seen to bulge into the lumen of the gastric glands. Other cell types were affected later and necrosis progressed from the surface into deeper parts of the mucosa. Mast cells and mucosal endocrine cells were relatively resistant, being mostly undamaged at the end of the shock period and later. The findings suggest that, during the shock, local formation of thrombi contributes to mucosal ischemia and ulcer formation, and that the cells at the neck region of the gastric glands form the locus of limited resistance to ulcerogenic effects.

0232 'LUMINAL NUTRITION' VERSUS 'FUNCTIONAL WORK-LOAD' AS CONTROLLERS OF MUCOSAL MORPHOLOGY AND EPITHELIAL REPLACEMENT IN THE RAT SMALL INTESTINE. (Eng.) Clarke, R. M. (Faculty

Medicine, Univ. Newcastle, Newcastle, N.S.W. 2308, Australia). *Digestion* 15(5):411-424; 1977.

The relation of small intestinal morphology and epithelial replacement to the secretory and absorptive workload that the epithelium performs was investigated in albino male Wistar rats. Isotonic solutions of substrate were infused into surgically unrestrained rats that fed normally via the "intestine-in-continuity." Infusion of glucose, galactose, or NaCl all caused a local increase in villus height, while α-methyl glucoside and mannose had no effect. Glucose, galactose, and α-methyl glucoside all stimulated a similar increase in counts of vincristine metaphases in microdissected crypts, although the absolute level of cell production was lower throughout the gut in glucose-infused rats. Sodium chloride infusion also caused a small stimulation of cell production locally, but a considerable increase in the uninfused intestine-in-continuity. Mannose infusion had a variable effect on cell nutrition" (nutrients in the lumen) as a controller of epithelial replacement in the rat small intestine, and suggest that a mechanism based on the workload of the epithelium may be more appropriate.

0233 THE PRODUCTION OF AN UNUSUAL TISSUE REACTION IN RABBIT BOWEL INJECTED WITH CROHN'S DISEASE HOMOGENATES. (Eng.) Simonowitz, D.; Block, G. E.; Riddell, R. H.; Kraft, S. C.; Kirsner, J. B. (Dept. Surgery, Univ. Chicago, 950 E. 59th St., Chicago, IL 60637). *Surgery* 82(2):211-218; 1977.

Attempts were made to reproduce evidence of a transmissible factor in Crohn's disease. Twenty New Zealand White rabbits received inoculum of tissue homogenates from the terminal ileum of normal subjects and patients with ulcerative colitis or Crohn's disease. This inoculum was injected into the wall of the ascending colon, and the animals were examined after 1 yr. Changes were noted consistently only in those animals receiving the Crohn's disease inoculum. These changes consisted of thickened bowel wall with increased mucosal folds, thickened mesenteric fat with some creeping, irregular areas of thin colonic mucosa, and hyperplastic mesenteric lymph nodes. The terminal ileum distant from the inoculum site was smooth with atrophic changes only in the Crohn's inoculated group of animals. These animals also had discrete collections of macrophages in colon or sacculus, mucosal and submucosal edema, and chronic inflammation of the colon. However, the characteristic features of Crohn's disease were not reproduced.

0234 MALIGNANT DEGENERATION OF EXPERIMENTAL ULCERATIVE COLITIS OF THE RAT FOLLOWING SUBCUTANEOUS INJECTION OF 1,2-DIMETHYLHYDRAZINE. (Ger.) Dahm, K.; Knipper, A.; Mitschke, H. (Abteilung Allgemeinchirurgie der Chirurgischen Klinik, Martinistr. 52, D-2000 Hamburg 20, W. Germany). *Langenbecks Arch. Chir.* 343(4):307-311; 1977.

Experiments were carried out in male Wistar rats to determine whether the colon is more susceptible to malignant transformation in the presence of ulcerative colitis than when it is intact. Ulcerative colitis was induced by treating the rats with 4% carrageenan in the drinking water. The colon-specific carcinogen 1,2-dimethylhydrazine (DMH, 19.3 mg/kg) was then administered s.c. daily for 7 weeks. The animals received carrageenan up until 6 weeks after the last injection of DMH. Seventeen of the 18 rats with carrageenan-induced ulcerative colitis developed multiple adenocarcinomas of the distal colon by 15 weeks after the last DMH injection. In addition to adenocarcinomas, squamous cell metaplasias were also present. Only 3 of 18 controls treated with DMH alone developed adenocarcinomas of the distal colon, and none of 12 animals treated with carrageenan alone developed adenocarcinomas; 1 of the 12 animals did develop an adenoma with marked dysplasia. The results suggest that, during ulcerative colitis, the rat colon is more susceptible to tumor induction than it is when intact.

0235 DIFFERENCES IN SURVIVAL OF MOUSE COLON CRYPTS AFTER WHOLE- OR PARTIAL-BODY IRRADIATION. (Eng.) Hamilton, E. (Imperial Cancer Res. Fund Lab., Lincoln's Inn Fields, London WC2A 3PX, England). *Int. J. Radiat. Biol.* 31(4):341-347; 1977.

The survival of mouse colon crypts after whole- and partial-body x-irradiation was studied by the microcolony technique. The D_0 for crypt survival was 266 rad after whole-body irradiation in air, but when the colon alone was irradiated, the D_0 was 340 rad. In mice that were breathing 95% oxygen, the D_0 values were 238 rad for whole-body and 302 rad for colon irradiation. The survival curves were all extrapolated to the same number, and the threshold dose was also increased with colon irradiation. There was therefore an enhancement of colon crypt survival of about 27% by local as opposed to whole-body irradiation. These results might be explained by a circulating repair promoter or by the production of a toxin after whole-body irradiation.

0236 ISOLATION OF THE CECAL MICROFLORA OF MICE AND COMPARISON BETWEEN THE GASTRO-INTESTINAL AND THE FECAL MICROFLORAS. (Eng.) Koopman, J. P.; Janssen, F. G. J.; van Druten, J. A. M. (Central Animal Lab., Catholic Univ. Nijmegen, Geert Grooteplein Noord 29, Nijmegen, Netherlands). *Z. Versuchstierkd.* 19(1/2):62-70; 1977.

The number of bacteria that could be cultured from the cecum of SPF mice was determined, and the gastrointestinal and fecal microfloras were compared. The recovery of cecum bacteria was determined by three bacteriological techniques: an aerobic technique, an anaerobic jar technique, and a strict anaerobic glove-box technique. The median values for the yields were 0.46%, 4.8%, and 37%, resp. Lactobacilli, staphylococci, and streptococci were present in relatively low levels (median values/g, resp., 9.3 x 10^8, 1.6 x 10^6, and 2.4 x 10^5). Subsequently, the recovery of cecum bacteria from CRF-mice and GF-mice associated with 10 *in vitro* cultured anaerobic (bacterial) strains (ex-GF) was determined using a strict anaerobic technique. These yields were compared with the results obtained in SPF-mice. The cecal weights were different. However, the microscopic counts per cecum were not significantly different among the three groups, i.e., 1.6×10^{10} (median values). Accordingly, the concentration of cecal bacteria was not equal in the three groups. The viable count as percentage of the total numbers of bacteria in the ceca of ex-GF, CRF, and SPF-mice was 54%, 44%, and 37%, resp. Within the three bacteriologically different groups, evidence for a positive correlation between cecal weight and microscopic count per cecum, resp., viable count per cecum was found. The bacterial concentrations per gram contents in stomach/small intestine, cecum/large intestine and feces were 2.1×10^{8}, 1.7×10^{10}, and 1.9×10^{10}, resp. The excretion of bacteria with the feces per 24 hr varied between 54% and 400% (median value 150%) of the number of bacteria present in the gastrointestinal tract.

0237 THE INFLUENCE OF ADRENOCEPTOR ACTIVITY ON CELL PROLIFERATION IN COLONIC CRYPT EPITHELIUM AND IN COLONIC ADENOCARCINOMATA.

(Eng.) Tutton, P. J. M.; Barkla, D. H. (Dept. Anatomy, Monash Univ., Clayton, Victoria, 3168, Australia). *Virchows Arch.* [*Cell Pathol.*] 24(2):139-146; 1977.

The effects of chemical sympathectomy and of the injection of amines or amine receptor blocking drugs on cell proliferation in colonic crypts and in dimethylhydrazine-induced colonic carcinomas were examined in male Sprague-Dawley rats using a stathmokinetic technique. In animals chemically sympathectomized by the injection of 6-hydroxydopamine (100 mg/kg, i.v.), cell proliferation essentially ceased in the colonic crypts but continued at a normal rate in the tumors. Stimulation of α-adrenoceptors by metaraminol (2.5 mg/kg) caused acceleration of cell proliferation in colonic crypts but not in tumors. Conversely, blockade of α-adrenoceptors by phentolamine (10 mg/kg) inhibited cell proliferation in crypts but not in tumors. The injection of epinephrine (1 mg/kg) inhibited cell proliferation in the tumors but not in colonic crypts, whereas blockade of β-adrenoceptors by propranolol (20 mg/kg) accelerated cell proliferation in tumors but not in colonic crypts. It is postulated that cell proliferation in the crypts of Lieberkuhn in rat colon resembles that in rat jejunum in being controlled by the autonomic nervous system. However, tumor cell proliferation does not appear to be subject to such regulation.

0238 PATHOGENESIS OF SHIGELLA DIARRHEA. VII. EVIDENCE FOR A CELL MEMBRANE TOXIN RECEPTOR INVOLVING β1→4-LINKED n-ACETYL-D-GLUCOSAMINE OLIGOMERS.

(Eng.) Keusch, G. T.; Jacewicz, M. (Mount Sinai Sch. Medicine, City Univ. New York, New York, NY 10029). *J. Exp. Med.* 146(2):535-546; 1977.

To determine whether mammalian cells possess a membrane receptor for *Shigella dysenteriae* 1 cytotoxin, the binding of this cytotoxin to HeLa cells in culture and to isolated rat liver cell membranes was studied by an indirect consumption assay of toxicity from the medium or by determination of cytotoxicity to the HeLa cell monolayer. Both liver cell membranes and HeLa cells removed toxicity from the medium during incubation, in contrast to WI-38 and Y-1 mouse adrenal tumor cells. Uptake of toxin was directly related to concentration of membranes added, time, and temperature, and indirectly related to the ionic strength of the buffer used. The chemical nature of the membrane receptor was characterized by using three principal approaches: (a) enzymatic sensitivity, (b) competitive inhibition, and (c) receptor blockade studies. The receptor was destroyed by proteolytic enzymes, phospholipases (which markedly altered the gross appearance of the membrane preparation), and by lysozyme, but not by a variety of other enzymes (galactose oxidase, β-galactosidase, neuraminidase). Of 28 carbohydrate and glycoprotein haptens studied, including cholera toxin and ganglioside, only the chitin oligosaccharide lysozyme substrates, per *N*-acetylated chitotriose, chitotetraose, and chitopentaose, were effective competitive inhibitors. Greatest inhibition was found with the trimer, *N*,*N*',*N*" triacetyl chitotriose. Of three lectins studied as possible receptor blockers, including phytohemagglutinin, concanavalin A, and wheat germ agglutinin, only the latter, which is known to possess specific binding affinity for *N*,*N*',*N*" triacetyl chitotriose, blocked toxin uptake. Evidence from all three approaches indicate that a glycoprotein toxin receptor exists on mammalian cells, with involvement of oligomeric β1→4-linked *N*-acetyl glucosamine in the receptor. This receptor is clearly distinct from the G_{M1} ganglioside thought to be involved in the binding of cholera toxin to the cell membrane of a variety of cell types susceptible to its action.

0239 HEPATIC BLOOD FLOW MEASUREMENT: A COMPARISON OF THE INDOCYANINE GREEN AND ELECTROMAGNETIC TECHNIQUES IN NORMAL AND ABNORMAL FLOW STATES IN THE DOG.

(Eng.) Teranaka, M.; Schenk, W. G. (Dept. Surgery, State Univ. New York at Buffalo, Buffalo, NY). *Ann. Surg.* 185(1):58-63; 1977.

Hepatic blood flow was measured simultaneously by the electromagnetic technique (EMF) and by clearance of a single injection of indocyanine green (ICG, 0.4-0.7 mg/kg body weight) in 9 normal dogs and 14 dogs in unsteady state following hemorrhage (the amount of acute blood loss ranged 0.5-1.0% of body weight) to establish the validity of the ICG method in both steady and unsteady states. Close correlation between the ICG clearance (25.3 ± 9.7 ml/kg body weight/min) technique and the EMF technique (26.3 ± 9.1 ml/kg body weight/min) under normal flow states was seen. However, under the unsteady condition (15 min bleeding), ICG indirect flow measurement (14.04 ± 4.8 ml/kg body weight/min) estimated only 71% of the actual instantaneous electromagnetic flow value of 19.0 ± 4.9 ml/kg body weight/min. It is suggested that while the EMF method continues to measure the actual total hepatic blood flow, the ICG method may measure the functional hepatic flow.

0240 EFFECTS OF BILE AND BILE ACIDS ON CULTURED HUMAN FIBROBLASTS. (Eng.) Trias, X.; Strebel, H. M.; Paumgartner, G.; Wiesmann, U. N. (Dept. Pediatrics, Univ. Bern, Freiburgstrasse 23, CH-3010 Berne, Switzerland). *Eur. J. Clin. Invest.* 7(3):189-194; 1977.

To determine whether impaired healing induced by leakage of bile is a factor responsible for complications after reconstructive bile duct surgery, the cytotoxicity of human bile, and its major bile acids, on cultured human fibroblasts was studied. The effects of bile and bile acids on cell morphology and growth, on synthesis and secretion of $^{35}SO_4$-mucopolysaccharides, and on release of a lysosomal enzyme were evaluated. Normal human fibroblasts derived from a standard culture strain (MRC-5) were grown to confluence and exposed to: (a) sterile human T-tube bile, (b) a mixture of bile acids resembling that of human bile, or (c) various concentrations of the glycine and taurine conjugates of cholic, chenodeoxycholic, or deoxycholic acid. Medium containing whole bile (total bile acid concentration 0.25, 0.75, or 1.6 mM) exerted time- and dose-dependent cytotoxic effects on morphology and growth and release of lysosomal enzyme. Synthesis and secretion of $^{35}SO_4$-mucopolysaccharides were markedly inhibited. The bile acid mixture exhibited the same time- and dose-dependent effects. The conjugates of deoxycholic acid were found to be the most toxic of the individual bile acids studied.

0241 THE ROLE OF TUBULAR REABSORPTION IN THE RENAL EXCRETION OF BILE ACIDS. (Eng.) Barnes, S.; Gollan, J. L.; Billing, B. H. (Univ. Alabama Medical Center, Birmingham, AL 35294). *Biochem. J.* 166(1):65-73; 1977.

To provide possible explanations for the bile acid composition in human cholestatic urine, the renal excretion of bile acids was studied in an isolated rat kidney preparation perfused with a protein-free medium. Tubular reabsorption exceeded 95% for both nonsulfated and sulfated bile acids at filtered loads of less than 30 nmol/min. At low filtered loads, the reabsorption of taurocholate and taurochenodeoxycholate was almost complete. Efficient reabsorption of taurochenodeoxycholate was maintained over a wider range of filtered loads than for taurocholate. These observations suggest that active transport may occur. At high filtered loads, saturation of reabsorption of taurocholate and taurochenodeoxycholate did not occur, which indicates that passive diffusion is involved in reabsorption. Active proximal-tubular secretion of bile acids was not demonstrated in competition experiments with *p*-aminohippurate. The fractional reabsorption of taurocholate, chenodeoxycholate, 3,7-disulfate, and chenodeoxycholate 7-monosulfate was decreased by the addition of taurochenodeoxycholate to the perfusate, so that their renal excretion was enhanced. This interaction between the bile acids for reabsorption may explain the different composition of bile acids in urine compared with that in plasma in cholestasis in man. Conjugated bilirubin decreased the fractional reabsorption of both taurocholate and taurochenodeoxycholate at low filtered loads (<30 nmol/min) but not at high filtered loads (400 nmol/min).

0283 ULTRASONIC DISTINCTION OF ABSCESSES FROM OTHER INTRA-ABDOMINAL FLUID COLLECTIONS. (Eng.) Doust, B. D.; Quiroz, F.; Stewart, J. M. (Medical Coll. Wisconsin, 8700 W. Wisconsin Ave., Milwaukee, WI 53226). *Radiology* 125(1):213-218; 1977.

To investigate the ultrasonic distinction of abscesses from other intra-abdominal fluid collections, the nature of 103 intra-abdominal fluid collections examined by ultrasound was determined by autopsy, needle aspiration, spontaneous drainage, or surgical exploration. Abscesses, chronic hematomas, lymphoceles, urinomas, cysts, and fluid-filled bowel loops were all approximately elliptical or circular in cross section. Collections of ascites had a very irregular outline. Bowel loops appeared as multiple circles, all of similar size. Chronic hematomas contained strongly echoing material, while lymphoceles, urinomas, renal and hepatic cysts, and collections of ascites were echo-free. One ovarian cyst into which there had been bleeding contained echoes. The walls of abscesses, chronic hematomas, and bowel loops were less sharp than the walls of other collections. Intrahepatic abscesses had more ragged walls than abscesses elsewhere. Ultrasonic characteristics of abscesses and hematomas overlapped. It is sometimes possible to distinguish the nature of the fluid by its ultrasonic properties, but atypical appearances are not rare.

0284 HEPTADECAPEPTIDE GASTRIN: MEASUREMENT IN BLOOD BY SPECIFIC RADIOIMMUNOASSAY. (Eng.) Dockray, G. J.; Taylor, I. L. (Dept. Physiology, Univ. Liverpool, Brownlow Hill, P.O. Box 147, Liverpool L69 3BX, England). *Gastroenterology* 71(6):971-977; 1976.

The characteristics of an antibody (designated L6) that has absolute specificity for heptadecapeptide gastrin are described. This antibody was found to bind G17, but not peptide fragments or molecular forms of gastrin comprising G17 with either amino acid deletions, or additions, at the carboxyl- and amino-terminals. In sera from patients with Zollinger-Ellison syndrome, the only form of gastrin revealed by L6 was compatible with G17, and there was good agreement between estimated G17 concentrations in serum analyzed by gel filtration and by direct radioimmunoassay using L6. Using L6 in conjunction with antibodies specific for carboxyl- and amino-terminals of G17, it was possible to measure concentrations of different forms of gastrin in the sera of normal subjects after a meal in greater detail than was previously possible. After a light meal consisting of eggs, toast, and Oxo, serum concentrations of G17 measured by L6 increased to a peak 20 min after feeding (Δ gastrin, 19 pM; n=17). In contrast, the concentration of G34 peaked at 50 min (Δ gastrin, 27 pM). Small amounts of amino-terminal fragments of G17 were present throughout the digestive period. Applying the known ratio of biological potencies of G34 and G17 for stimulation of acid secretion in man, it is estimated that G17 accounts for about 75% of the biological activity in blood after a meal, even though G34 is present in higher molar concentrations.

0285 LYSOZYME LEVELS IN CHRONIC INFLAMMATORY BOWEL DISEASES. (Ger.) Rollinghoff, W.; Brandes, J. W.; Ehms, H.; Miller, B.; Schmulling, R. M.; Tischendorf, F. W.; Malchow, H. (Abt. Innere Medizin I, Otfried-Muller-Strasse, D-7400 Tubingen, W. Germany). *Klin. Wochenschr.* 55(5):225-230; 1977.

Urinary and serum lysozyme concentrations were determined by the lysoplate method of Osserman in 101 patients with Crohn's disease and 26 patients with ulcerative colitis and compared to 38 normal controls. Of the 101 patients with Crohn's disease, 29 showed changes of the small intestine, 31 had involvement of the small and large colon, and 16 showed involvement of the colon, 5 of the duodenum, and 1 of the stomach. At the time of the study, 14 patients were treated with prednisolone, 18 with salazopyrine, 23 with both the preceding agents, and 7 azathioprine; 28 had no therapy. Of the 26 patients with ulcerative colitis, the colon was extirpated in 3, 20 received salazopyrine, 1 received prednisolone, 4 received both of the latter 2 drugs, and 4 had no therapy. The mean serum lysozyme level of the patients with Crohn's disease was 8.2 ± 2.6 μg/ml as compared with 8.6 ± 2.9 μg/ml for the patients with ulcerative colitis and 8.4 ± 1.8 μg/ml for controls; no significant differences were noted between the patients and controls. Furthermore, no correlation between serum lysozyme levels and the disease activity index was found. However, serum lysozyme levels were significantly higher in patients with Crohn's disease of the small and large bowel (9.5 ± 3.5 μg/ml) than in patients with involvement of the small bowel only (8.1 ± 2.4 μg/ml) or operated patients (7.5 ± 1.5 μg/ml). The mean urinary lysozyme levels in 74 patients with Crohn's disease was 0.9 ± 2.1 μg/ml (normal value 0.9 ± 0.9 μg/ml) as compared with 0.1-16.6 μg/ml for 26 patients with ulcerative colitis. The results suggest that the determination of serum and urinary lysozyme levels is unsuitable for the differential diagnosis of inflammatory bowel disease and for assessment of disease activity.

GASTROINTESTINAL DISEASES

ESOPHAGUS

0309 RESPONSE OF LOWER ESOPHAGEAL SPHINCTER PRESSURE TO BEEF SOUP OR AOC-TETRAPEPTIDE STIMULATION IN ESOPHAGITIS. (Eng.) Nagasaki, A.; Ishimori, A.; Masamune, O.; Yamagata, S. (Tohoku Univ. Sch. Medicine, Sendai, Japan). *Tohoku J. Exp. Med.* 121(1):91-97; 1977.

Lower esophageal sphincter (LES) pressure in the resting state and after stimulation with beef soup or anodal opening contraction (AOC) tetrapeptide were measured in healthy subjects and diseased patients by an infused open-tip method. The mean basal LES pressures in healthy subjects and in patients with gastric ulcer, duodenal ulcer, scleroderma without gastrointestinal symptoms, and esophageal hiatal hernia without esophagitis were 13.1 ± 1.7, 12.8 ± 1.4, 13.7 ± 1.4, 12.0, and 12.8 ± 1.4 cm water, resp. (differences not significant). In two cases of Zollinger-Ellison syndrome, the resting LES pressure was 24.1 ± 0.5 cm, which was significantly ($p<0.001$) higher than that in controls. In cases of esophagitis with hiatal hernia, esophagitis without hiatal hernia, and esophagitis following Billroth II gastrectomy, the LES pressure levels were 10.2 ± 1.2 ($0.001<p<0.01$), 10.1 ± 0.9 ($0.001<p<0.01$), and 6.9 ± 1.2 cm ($p<0.001$), resp., significantly lower than in controls. In cases of esophagitis, the resting LES pressure and corresponding fasting plasma gastrin level tended to be lower than those in healthy subjects, but the reverse was true in cases of Zollinger-Ellison syndrome. When 200 ml beef soup was infused into the stomach, the peak LES pressures of healthy subjects and patients with esophagitis were 25.7 ± 0.5 and 17.1 ± 1.8 cm, resp. The peak percentage response to the resting LES pressure in these two groups was 221.0 ± 4.2 and 180.5 ± 10.5, resp. This implies that the peak LES pressure and the peak percentage response in the LES pressure were lower in esophagitis patients than in healthy subjects. After the i.v. administration of 0.3 or 0.5 μg/kg of tetrapeptide, these parameters were again lower in esophagitis patients than in controls. It is concluded that there are some factors other than gastrin that make the LES pressure lower in esophagitis patients than in controls.

0310 GASTRO-OESOPHAGEAL SPHINCTER PRESSURE, MOTILITY AND ACID CLEARING. A STUDY OF HIATUS HERNIA PATIENTS AND NORMAL SUBJECTS, AND OF THE EFFECT OF A MODIFIED BELSEY MK IV REPAIR ON THE RESULTS OF THE MANOMETRIC AND ACID-CLEARING TESTS. (Eng.) Boesby, S. (Odense Sygehus, DK-Odense, Denmark). *Scand. J. Gastroenterol.* 12(4): 407-416; 1977.

The results of manometric and acid-clearing studies of patients with hiatal hernia were compared with those of normal subjects, and the effect of a modified Belsey MK IV repair for hiatal hernia on the results of the manometric and acid-clearing studies was evaluated. Basal gastroesophageal sphincter pressure was recorded in 68 patients with symptomatic, radiologically verified sliding hiatal hernia, and in 37 healthy subjects. The diameter of the probe was 2.5 mm, and the flow rate 0.5 ml/min. Mean sphincter pressure was lower in patients (6 mm Hg) than in normal subjects (15 mm Hg). In 32% of the patients, the sphincter pressure was within normal range (8-24 mm Hg), whereas in 68% it was lower than in the normal subjects. There seemed to be no relationship between sphincter pressure and severity of symptoms. Esophageal acid clearing was investigated in 57 of the patients and in 26 of the normal subjects. Normal subjects cleared the bolus of acid in an average of 10 swallows (range 4-16). In patients, the incidence of prolonged clearing was greater, but the acid-clearing ability did not seem to be related to the degree of severity of the symptoms. A manometric study was carried out in 45 patients and an acid-clearing study was carried out in 40 patients, before and 3 months after a modified Belsey MK IV repair. The mean postoperative sphincter pressure was higher (10 mm Hg) than the preoperative mean (6 mm Hg), but was still lower than the normal mean. Significant changes in acid-clearing ability were not demonstrated. The results are inconclusive with regard to the importance of esophageal motility disturbances for the symptomatology and acid-clearing ability. Thirty-seven of 45 patients became asymptomatic, and all but one of the remaining patients improved.

0311 FUNDOPLICATION FOR THE TREATMENT OF GASTROESOPHAGEAL REFLUX IN HIATAL HERNIA. (Eng.) Rossetti, M.; Hell, K. (Kantonsspital, CH-4410 Liestal, Switzerland). *World J. Surg.* 1(4):439-444; 1977.

Experience with 1,400 patients who underwent fundoplication for the treatment of reflux in hiatal hernia was reviewed to determine the correct indications for surgery. These indications include (a) a retrosternal burning sensation (in 90% of cases), (b) objective confirmation of reflux by means of x-ray and endoscopic examination, together with biopsy examination of the esophageal mucosa and gastric acid evaluation, and (c) evidence of organic complications, such as endobrachyesophagus with ulcerostenotic changes at the junction between the esophageal and gastric mucosa. Long-term follow-up of 590 patients with simple reflux esophagitis who underwent fundoplication showed that 87.5% were symptom free. In 44 patients with complicated gastroesophageal reflux disease, fundoplication produced clinical healing in 84.1%.

0335 IMMUNOHISTOCHEMICAL INVESTIGATION OF GASTRIN-PRODUCING CELLS (G CELLS): THE DISTRIBUTION OF G CELLS IN RESECTED HUMAN STOMACHS. (Eng.) Stave, R.; Brandtzaeg, P. (Rikshospitalet, Oslo, Norway). *Scand. J. Gastroenterol.* 11(7):705-712; 1976.

Direct immunofluorescence with rhodamine-labeled rabbit antigastrin IgG conjugate was used to systematically map the G-cell distribution in resected stomachs from eight gastric ulcer patients and eight duodenal ulcer patients with uremia. G cells were not found in the body of the stomachs. A low number of G cells, which amounted to about 10 G cells per mucosal unit (MU, 6 µm thick and 1 mm wide block of tissue from the muscularis mucosae to the surface epithelium) occurred in a transitional zone at the proximal border of the antrum in both gastric ulcer and duodenal ulcer patients. No significant difference was found between the number of G cells per mucosal unit at various levels of the antrum in gastric ulcer patients; G cells/mucosal unit ranged from about 40-50 in these cases. In duodenal ulcer patients with uremia, there was a significant increase in the G cell number from the proximal (about 40 cells/MU) to the middle antrum (about 55 cells/MU, $0.02<p<0.05$) and especially from the proximal to the distal antrum (about 80 cells/MU) ($p<0.01$). There was no significant difference in the circumferential distribution of antral G cells between the two groups of patients. Statistically significant differences ($0.02<p<0.05$) between the two patient groups appeared for G cell counts in the distal third part of the antrum, with the number of G cells/MU being about 50 for gastric ulcer patients and about 80 for duodenal ulcer patients. The proximal end of the duodenum contained considerably fewer G cells (about 10 cells/MU in both patient groups) than the antrum. The results confirm the reported preponderance of G cells in the middle and basal third of the antral mucosa, although no conclusions are made concerning the difference in antral G cell distribution in the two patient groups.

0336 MENETRIER'S DISEASE: EFFECT OF MEDICAL AND SURGICAL VAGOTOMY. (Eng.) Russell, I. J.; Smith, J.; Dozois, R. R.; Wahner, H. W.; Bartholomew, L. G. (Mayo Graduate Sch. Medicine, Univ. Minnesota, Rochester, MN). *Mayo Clin. Proc.* 52(2):91-96; 1977.

The case of a 62-yr-old woman with incapacitating atherosclerotic vascular occlusive disease who was found to have severe hypoproteinemia as a result of Menetrier's disease is described. That diagnosis was suspected on roentgenographic and gastroscopic examinations and confirmed by examination of full-thickness surgical gastric biopsy specimens. The protein loss from the stomach was significantly decreased by treatment with trimethaphan (0.3-0.5 mg/min, 4.5 hr, i.v.) and atropine (0.5 mg every 2 hr, i.m.), and a proximal gastric vagotomy was carried out at the time of endarterectomy. Subsequent protein turnover studies suggested that there was a significant decrease in protein loss by the stomach; plasma radioactive albumin clearance was 90 ml/day immediately after surgery and 77 and 33 ml/day at 4 and 12 months postoperatively, resp., and gastric clearance was 41 ml/24 hr at 12 months after surgery. Further evaluation of the possible role of medical and surgical vagotomy in this disease seems warranted.

0337 GASTRIC MUCOSAL POLYPS IN PERNICIOUS ANAEMIA. (Eng.) Elsborg, L.; Andersen, D.; Myhre-Jensen, O.; Bastrup-Madsen, P. (Aarhus Amtssygehus, DK-8000 Aarhus C, Denmark). *Scand. J. Gastroenterol.* 12(1):49-52; 1977.

Sixty-eight patients with pernicious anemia were followed up for 4 yr to determine whether gastric mucosal polyps were present. Gastric polyps were observed in 25 patients. In nine patients the polyps completely vanished in a year or two. The number of polyps decreased during the observation period in two patients. New polyps developed in five patients in whom gastroscopy had showed none. None of these polyps underwent malignant transformation during the period of observation, and by histological examination they were classified as non-neoplastic "regenerative" benign polyps in an atrophic gastric mucosa. The surgical attitude to these non-neoplastic gastric polyps in pernicious anemia should be restrictive.

Peptic Ulcers

0363 BASAL GASTRIC SECRETION: REPRODUCIBILITY AND RELATIONSHIP WITH DUODENAL ULCERATION. (Eng.) Faber, R. G.; Hobsley, M. (Middlesex Hosp. Medical Sch., London, England). *Gut* 18(1):57-63; 1977.

Basal gastric secretion was examined in control subjects (C), duodenal ulcer patients (DU), and DU patients after vagotomy (DU + V, with or without a drainage procedure). Secretion in terms of observed gastric juice volume (Vo) and of gastric juice volume corrected for pyloric losses and duodenal reflux (Vg) was significantly ($p<0.01$) less in the second than in the first half-hour of a 1-hr basal collection; C, DU, and DU + V groups showed Vo values of 4.387, 2.739, and 4.914 ml/hr, resp., and Vg values of 7.537, 7.242, and 4.353 ml/hr, resp. Basal acid output (BAO) was significantly ($p<0.05$) less also in the second half-hour of a 1-hr basal collection in controls and DU + V patients; the BAO values for C, DU, and DU + V groups were 2.102, 1.639, and 2.863, mM/hr, resp. The reproducibility of the second half-hour basal collections taken on two different occasions from DU and DU + V patients was poor; the 95% tolerance limits of the difference between the two tests in terms of Vo, titratable acidity (H^+), BAO, and VG were approximately 101.2 ml/hr, 42.2 mM, 9.28 mM/hr, and 107.6 ml/hr, resp., for DU patients and 106.0 ml/hr, 46.0 mM, 7.28 mM/hr, and 93.8 ml/hr, resp., for DU + V patients. When expressed in terms of basal secretion in excess of the upper 95% tolerance limits of C subjects, the percentages of DU patients exceeding these limits were 17 for Vo, 0 for H^+, 29 for BAO, and 19 for Vg. The percentages of DU + V patients with recurrent ulcer after vagotomy exceeding the 95% tolerance limits of DU + V patients without symptoms were 25 for Vo, 0 for H^+, 50 for BAO, and 25 for Vg. By all indices of secretion, basal gastric secretion in DU patients was significantly ($p<0.005$) greater than in C subjects or in asymptomatic DU + V patients. Secretion by all indices was also significantly ($p<0.05$) greater in recurrent ulcer DU + V patients than in asymptomatic DU + V patients. When changes in basal secretion were examined before and after vagotomy, only in terms of Vg was there a significant ($p<0.01$) difference between the two groups. The overlap in the results from different groups of patients was so great in general that basal secretion could not be ascribed an etiological role in the majority of patients with duodenal ulcer.

0364 THE ROLE OF THE BETA-ADRENERGIC RECEPTOR IN THE SECRETION OF GASTRIN: STUDIES IN NORMAL SUBJECTS AND IN PATIENTS WITH DUODENAL ULCERS. (Eng.) Brandsborg, O.; Brandsborg, M.; Christensen, N. J. (Kommunehospitalet, Aarhus C, Denmark). *Eur. J. Clin. Invest.* 6(5):395-401; 1976.

The role of beta-adrenergic receptors in gastrin secretion was studied in 8 normal men and 11 patients with duodenal ulcer. The i.v. infusion of isoproterenol (2 µg/min, 20 min) increased the serum gastrin concentration more in the patients with a duodenal ulcer than in the healthy subjects, and the differences were significant whether the absolute values were compared (mean rise 12 ng/l in controls versus 82 ng/l after isoproterenol, $p<0.01$) or the increase in serum gastrin expressed as a percent of the basal concentration was used (52% versus 94%, $p<0.05$). The rise in pulse rate, blood glucose concentration, and serum insulin was the same in both groups. Gastrin secretion was also increased significantly more in the patients than in the control subjects after a beef meal. Basal serum gastrin concentrations were higher in the patients than in the control subjects and correlated to the rise in serum gastrin during both tests in the duodenal ulcer patients. Isoproterenol- and meal-stimulated gastrin secretion, expressed as percent of the basal value, was twice as high in the patients as in the control subjects. The combined administration of isoproterenol and the meal had an additive effect on the rise in serum gastrin. Isoproterenol-stimulated gastrin secretion was completely suppressed by propranolol, which had no effect on meal-stimulated gastrin secretion. It is concluded that the mechanism of gastrin hypersecretion in patients with a duodenal ulcer does not involve a specific abnormality of the beta-adrenergic receptor or the receptor that recognizes proteins and their digested products. There is no established role of beta-adrenergic receptor activity in the hypersecretion of gastrin in patients with duodenal ulcers. It is suggested that the beta-adrenergic receptor may have some function unrelated to the acute secretory response of gastrin.

0365 EFFECTS OF PARENTERAL SECRETIN-CHOLECYSTOKININ AND OF DUODENAL ACID PERFUSION ON ASTRIC SECRETION IN DUODENAL ULCER PATIENTS. (Eng.) utt, J.; Yoshida, T.; Fleshler, B. (800 Stadium Rd., olumbia, MO 65201). *Am. J. Dig. Dis.* 22(4):371-78; 1977.

o investigate the possibility that failure of en-ogenous hormone(s) release by duodenal acidification ight play a role in the genesis of peptic ulcer isease, the effect of parenteral secretin-cholecys-okinin and duodenal acid perfusion on broth-stimu-ated gastric acid secretion was studied in 11 duo-enal ulcer patients. Statistically significant inhibition occurred in both experimental conditions. The effect of secretin-cholecystokinin was more marked than the effect of duodenal acid perfusion. A poorly responsive subgroup of patients appeared to be responsible for the diminished inhibitory effect of duodenal acid perfusion. In this poorly responsive group there was a diminished duodenal volume response as well as diminished duodenal acid clearing. It is concluded that there may exist a diminished release of gastrointestinal hormones such as secretin and cholecystokinin in certain duodenal ulcer patients.

0366 DIFFERENCES IN ANTRAL RESPONSE TO MEAT EXTRACT IN DUODENAL ULCER PATIENTS. (Eng.) Perreault, C.; Coutsoftides, T.; Himal, H. S. (Dept. Experimental Surgery, McGill Univ., Montreal, Canada). *Am. J. Gastroenterol.* 67(4):348-353; 1977.

The pathogenesis of duodenal ulcer formation and its relation to acid secretion (basal, antral, and peak) was studied in 59 duodenal ulcer and 12 normal subjects. Antral function was assessed by instilling meat extract solution into the stomach and then measuring acid and serum gastrin output. Peak acid output was significantly higher ($p<0.001$) in the patients (34.14 ± 1.64 mEq/l) than in the normal subjects (20.08 ± 3.79 mEq/l), but basal and peak gastrin values were not significantly different between the two populations. Two groups of duodenal ulcer patients were thus identified: (1) antral responders (31), in whom meat extract caused a significant ($p<0.001$) increase in serum gastrin output (from a basal value of 66.7 ± 7.1 to 153.3 ± 20.5 meat extract-stimulated gastrin output/ml) and acid output (from 4.57 ± 0.54 to 13.33 ± 1.16 mEq/l), and (2) antral nonresponders (28), in whom meat extract did not lead to a significant elevation in gastrin and acid output. The separation of duodenal ulcer patients into those who have or do not have a hyperfunctioning gastric antrum allows one to select the type of operation for each patient. In patients with a hyperfunctioning antrum, vagotomy and antrectomy are suggested; in those with a normal functioning antrum, vagotomy and drainage would be the procedures of choice.

SMALL INTESTINE

0388 THE INTERDIGESTIVE MOTOR COMPLEX OF NORMAL SUBJECTS AND PATIENTS WITH BACTERIAL OVERGROWTH OF THE SMALL INTESTINE. (Eng.) Vantrappen, G.; Janssens, J.; Hellemans, J.; Ghoos, Y. (Dept. Medical Res., Univ. Leuven, Leuven, Belgium). *J. Clin. Invest.* 59(6):1158-1166; 1977.

To investigate whether the interdigestive motor complex identified in several animal species occurs in man, intraluminal pressures were measured in the gastric antrum and at different levels of the upper small intestine in 18 normal subjects. In all normal subjects, the activity front of the interdigestive motor complex was readily identified as an uninterrupted burst of rhythmic contraction waves that progressed down the intestine, and that was followed by a period of quiescence. Quantitative analysis of various parameters of the complex and simultaneous radiological and manometrical observations revealed that it resembled closely the canine interdigestive motor complex. To test the hypothesis that disorders of this motor complex may lead to bacterial overgrowth in the small intestine, similar studies were carried out in 18 patients with a positive $^{14}CO_2$ breath test and in 9 controls with a normal $^{14}CO_2$ breath test. All but five patients had normal interdigestive motor complexes. The five patients in whom the motor complex was absent or greatly disordered had bacterial overgrowth, as evidenced by $^{14}CO_2$ bile acid breath tests before and after antibiotics. These studies establish the presence and define the characteristics of the normal interdigestive motor complex in man. They also suggest that bacterial overgrowth may be due to a specific motility disorder, i.e., complete or almost complete absence of the interdigestive motor complex.

0389 JUXTAPAPILLARY DUODENAL DIVERTICULA AND ABNORMALITIES BY ENDOSCOPIC RETROGRADE CHOLANGIO-PANCREATOGRAPHY (ERCP). (Eng.) Osnes, M.; Myren, J.; Lotveit, T.; Swensen, T. (Ulleval Hosp., Oslo 1, Norway). *Scand. J. Gastroenterol.* 12(3): 347-351; 1977.

The relationship between juxtapapillary duodenal diverticula and changes demonstrated by endoscopic retrograde cholangiopancreatography (ERCP) was investigated. In 174 patients, the biliary and pancreatic ducts were demonstrated by ERCP. Juxtapapillary diverticula were found in 5 of 84 patients with normal duct systems. In 90 cases of ductal abnormalities due to biliary concrements, dilated common bile duct, and pancreatitis, diverticula were found in 35. In patients with abnormalities in both duct systems, diverticula were found in 52%, and in patients with changes in one duct system, diverticula were found in 33%. The difference in occurrence of diverticula in patients with normal duct systems and pathological duct systems was statistically significant ($p<0.02$). The findings indicate a correlation between juxtapapillary diverticula and pathological changes due to biliary concrements, dilated common bile duct without concrements, and pancreatitis.

0390 CURRENT STATUS OF DIAGNOSIS AND MANAGEMENT OF STRANGULATION OBSTRUCTION OF THE SMALL BOWEL. (Eng.) Shatila, A. H.; Chamberlain, B. E.; Webb, W. R. (Southland Medical Building, Suite 128, 6867 Pearl Rd., Cleveland, OH 44130). *Am. J. Surg.* 132(3):299-303; 1976.

Consecutive case records of 50 patients treated for strangulation obstruction of the small bowel are compared with those of 53 patients treated for simple small bowel obstruction. Hernias were the most frequent cause of obstruction in the strangulation group (64%), followed by postoperative adhesions (32%). Postoperative adhesions were the most frequent cause of obstruction in the simple obstruction group (66%) followed by intra-abdominal malignancies (9.0%) and hernias (7.5%). The early differentiation between simple and strangulation obstruction by clinical criteria and laboratory tests was difficult, and strangulation obstruction was suspected preoperatively in only 25 strangulation cases. Abdominal pain, vomiting, abdominal distention, tachycardia, fever, abdominal tenderness, abdominal rebound, and palpable abdominal mass were common to both groups, with incidences of 96, 79, 68, 34, 19, 71, 8, and 9%, resp., in the simple obstruction group and incidences of 90, 86, 60, 44, 24, 86, 10, and 62%, resp., in the strangulation group. Abdominal wall rigidity (8%), shock (16%), hypothermia (10%), and rectal bleeding (8%) occurred only in the strangulation group and only in patients with late obstruction. Leukocytosis (WBC>11,000/mm^3), 79% neutrophilia or greater, elevated SGOT (>40 µU/ml), elevated LDH (>225 µU/ml), and elevated serum amylase (>200 Somogyi U/ml) were found in 45, 50, 32, 10, and 0%, resp., of the simple obstruction cases and in 62, 70, 46, 37, and 10%, resp., of the strangulation cases. Of 26 patients who had gangrenous bowel preoperatively, the classic signs of strangulation, i.e., fever, leukocytosis, and tachycardia, were absent in 70, 42, and 42%, resp., of these patients. Postoperative mortality was 8% in the strangulation group and 0% in the simple obstruction group. Overall morbidity was 42% in the strangulation group, with wound infections (10 cases), urinary tract infections (8 cases), and pulmonary complications (6 cases) being the most common. Early operation after rapid resuscitation is absolutely indicated for virtually all patients with acute mechanical small bowel obstruction. Patients with obstruction secondary to intra-abdominal carcinomatosis or radiation enteritis and patients with multiple recurrent episodes of intestinal obstruction secondary to adhesions may be excluded and benefit from a more conservative course of therapy.

0391 FAT DIGESTION AFTER JEJUNOILEAL BYPASS OPERATION FOR OBESITY. (Eng.) Sorensen, T. I. A.; Krag, E. (Gentofte Hosp., Univ. Copenhagen, Copenhagen, Denmark). *Scand. J. Gastroenterol.* 11(5):491-495; 1976.

To investigate the etiology of steatorrhea following jejunoileal bypass, fat digestion in the upper jejunum was studied in 12 obese patients treated by jejunoileal bypass. Either 12.5 cm or 37.5 cm of the distal ileum was included in the bypass. The jejunum was intubated, and a test meal was ingested before and 1-2 months after operation. Jejunal aspirates were heated immediately to destroy lipase, pooled, and assayed for dilution marker, bile acids, and total fat. Lipolytic products were determined by thin-layer chromatography and densitometry. The micellar phase was achieved by ultracentrifugation and analyzed for total fat. Both the bile acid concentration and lipolysis decreased after both bypass operations ($p<0.05$ and $p<0.01$, resp.). In accordance with this, micellar solubilization of fat was impaired after the operation ($p<0.01$ after the first type of bypass; $p<0.05$ after the second type.). Bile acid concentration and micellar solubilization were lower after bypass with a long ileal loop than after bypass with a short ileal loop. Fat absorption in the duodenum and upper jejunum did not change significantly after any of the operations. Jejunoileal bypass impairs fat digestion, but this does not contribute significantly to postoperative fat malabsorption.

SMALL INTESTINE

Malabsorption

0423 JEJUNAL PERFUSION OF SIMPLE AND CONJUGATED FOLATES IN CELIAC SPRUE. (Eng.) Halsted, C. H.; Reisenauer, A. M.; Romero, J. J.; Cantor, D. S.; Ruebner, B. (Sch. Medicine, Univ. California, Davis, CA 95616). *J. Clin. Invest.* 59(5):933-940; 1977.

The intestinal absorption of [^{3}H]pteroylmonoglutamate (simple folic acid) and pteroyl-μ[^{14}C]glutamyl-γ-hexaglutamate ([^{14}C]PG-7, conjugated folic acid) was assessed by the method of jejunal perfusion in five patients with proven celiac sprue who were studied after a gluten-containing or a gluten-free diet, and in nine normal subjects. The luminal disappearance of each folate was markedly impaired after exposure of the patients to dietary gluten in comparison with that in patients on a gluten-free diet ($p<0.02$ for [^{3}H]PG-1, $p<0.01$ for [^{14}C]PG-7), but the levels in the celiac patients on the gluten-free diets did not come within the range found in the normal subjects. Column chromatography of the luminal aspirates revealed similar spectra of hydrolytic products of {^{14}C]PG-7, whereas the fraction of the distal aspirate chromatogram appearing as pteroyl-μ[^{14}C]glutamyl-γ-monoglutamate ([^{14}C]-PG-1) was similar in all three groups. By accounting for the variable effects of absorption on the luminal appearance of [^{14}C]PG-1 and by correcting for mucosal hydrolysis that was not followed by release of [^{14}C]PG-1 to the luminal contents, the calculated rate of *in vivo* hydrolysis of [^{14}C]-PG-7 to [^{14}C]PG-1 was found to be impaired in both celiac sprue groups, with significant improvement on treatment. In mucosal biopsies from the sprue patients, the *in vitro* activity of folate conjugase in whole homogenates was higher and the activity of disaccharidase lower than in a group of 12 normal mucosal biopsies. These *in vitro* data suggest that the predominant cellular location of mucosal folate conjugase is different from that of disaccharidase, whereas comparison with the results of *in vivo* hydrolysis suggests that measurement of the enzyme in whole mucosal homogenates overestimates its significant digestive activity. These studies indicate that the mucosal lesion of celiac sprue significantly limits the intestinal absorption of both simple and conjugated folate, and that malabsorption of conjugated folate results from a combination of impaired hydrolysis and decreased mucosal uptake of hydrolytic product.

0424 PHARMACOKINETICS OF SALICYLATE AND INDOMETHACIN IN COELIAC DISEASE. (Eng.) Parsons, R. L.; Kaye, C. M.; Raymond, K. (Guy's Hosp., St. Thomas St., London SE1 9RT, England). *Eur. J. Clin. Pharmacol.* 11(6):473-477; 1977.

To determine whether the abnormal plasma concentration/time curve of lipid soluble drugs seen in celiac disease is related to their pKa, the plasma concentrations of salicylate and indomethacin were measured after a single p.o. dose of aspirin (600 mg) or indomethacin (50 mg) in 12 starved normal subjects and in 12 adult patients with celiac disease. The absorption of salicylate in the celiac patients was faster than that in the normal subjects. The plasma concentration/time curve of indomethacin in both groups was similar during the absorption phase, but there were significant differences between the groups in its elimination. The abnormal absorption pattern of salicylate in celiac disease does not appear to be related to its pKa. Possible causes of the difference in salicylate absorption include changes in gastric emptying or altered small intestinal permeability.

0425 DEPRESSED CELL-MEDIATED IMMUNITY IN COELIAC DISEASE. (Eng.) Scott, B. B.; Losowsky, M. S. (St. James' Hosp., Leeds, England). *Gut* 17(11): 900-905; 1976.

Phytohemagglutinin (PHA)-induced lymphocyte transformation was used to assess the integrity of cell-mediated immunity (CMI) in 10 untreated celiac patients on a normal diet, 14 celiac patients treated with a gluten-free diet (GFD), and 13 healthy controls. Untreated celiac patients had significantly reduced transformation compared with controls in both autologous and pooled AB serum ($p<0.02$). Treated celiac patients had significantly reduced transformation in autologous serum ($p<0.05$) but not in pooled AB serum ($p>0.1$). Responses to PHA in treated patients were significantly higher than in untreated patients in pooled AB serum ($p=0.03$) but not in autologous serum ($p=0.06$). Responses to PHA in pooled AB serum were significantly higher than in autologous serum in patients on a GFD ($p=0.04$) but not in celiac patients on a normal diet ($p=0.16$). The improvement in CMI after treatment was particularly apparent in six celiac patients studied on both a normal diet and a GFD. Lymphocytotoxic antibodies were detected in only three patients, and lymphocyte transformation was more depressed in autologous serum in two of these patients. No correlation was established between lymphocyte transformation and nutritional deficiency. Only 22% of the celiac patients had positive Mantoux tests compared with 85% of the controls ($p<0.001$). Two patients who were tested before and after *Bacillus Calmette-Guerin* vaccination remained negative, although one had responded well to the GFD. Mantoux tests were as commonly negative in treated as in untreated patients. CMI depression in celiac disease may be partly explained by an undefined depressing serum factor. If depressed immunity in celiac disease is related to the development of malignancy, the case for a strict GFD in all patients is reinforced by the improved CMI as assessed by lymphocyte transformation in GFD-treated patients.

0426 CELL-MEDIATED AUTOIMMUNITY IN COELIAC DISEASE. (Eng.) Scott, B. B.; Losowsky, M. S. (Univ. Dept. Medicine, St. James' Hosp., Leeds, LS9 7TF, England). *Clin. Exp. Immunol.* 26(2):243-246; 1976.

Lymphocyte transformation in response to a crude freeze-dried preparation of whole jejunal mucosa was studied in 15 patients with celiac disease and compared with the findings in 15 age-matched controls. The transformation ratio was markedly increased in three patients. The patients with the highest and third highest ratios were on a gluten-free diet, while the other responders were on a normal diet. These observations suggest the possible existence of cell-mediated autoimmunity to jejunal mucosa in some patients with celiac disease and might be relevant to the development of some of the complications of the disease.

0439 GEOGRAPHIC PATTERNS OF LARGE BOWEL CANCER IN THE UNITED STATES. (Eng.) Blot, W. J.; Fraumeni, J. F.; Stone, B. J.; McKay, F. W. (Natl. Cancer Inst., U.S. Dept. Health, Education, and Welfare, Bethesda, MD 20014). *J. Natl. Cancer Inst.* 57(6):1225-1231; 1976.

Age-adjusted colon and rectal cancer mortality rates during 1950-1969 were correlated by sex and race (white and nonwhite) with demographic data for 3,056 counties of the contiguous United States. Mortality from both types of cancer was consistently elevated in counties with large populations and with higher income and education levels. Geographically, mortality rates for both types of cancer were highest in the northeast and lowest in the southeast. The death rates among whites with colon cancer were generally higher for women than for men, except in highly populous counties where the situation was reversed. Colon cancer mortalities were highest in counties with relatively high percentages of people of Irish, Czechoslovak, or German descent. The death rate for rectal cancer among whites was greater among men than among women. However, the male/female mortality ratio for rectal cancer rose with increasing population size, similar to a pattern seen for colon cancer. Rectal cancer death rates among whites were highest in counties with a high percentage of residents of Greek, Irish, and German stock. Colorectal cancer mortality rate patterns for nonwhites of both sexes resembled those for whites. Colon cancer mortality rates in both sexes were higher among whites than nonwhites, especially in the north. Rectal cancer mortality rates in men likewise were higher among whites than nonwhites in the north; however, no racial differences were found in the south. For women, the rectal cancer death rates were slightly higher among whites in the north but slightly higher among nonwhites in the south. Colon cancer mortality among nonwhites was higher in women than in men, except in populous northern counties where the rates were about equal. Rectal cancer was more common among men than among women in nonwhites, though the sex difference was not as great as it was among whites. A survey on dietary habits by region and on alcohol sales by county failed to show an impressive correlation with bowel cancer mortality. The geographical variations in colorectal cancer mortality rate may be helpful in the identification of dietary and other environmental determinants of large bowel tumors.

0440 LINCOMYCIN-CLINDAMYCIN COLITIS IS NOT AN ENTITY. (Eng.) Devroede, G.; Poisson, J.; Madarnas, P.; Beaudry, R.; Haddad, H.; Strom, B.; *et al.* (Centre Hospitalier Universitaire Sherbrooke, Quebec J1H 5N4, Canada). *Can. J. Surg.* 20(4):326-335; 1977.

From 1969 to 1975, 10 cases of pseudomembranous colitis (PC, group I) and 13 cases of nonpseudomembranous colitis (NPC, group II) developed as a result of ingestion of antibiotics. All patients recovered after the administration of clindamycin plus steroids. During this period, an erroneous diagnosis of PC was made in three patients (later diagnosed as having ulcers) who had not received antibiotics but had focal accumulation of pus on the rectal mucosa and were chronically ill. The penicillin class of antibiotics was responsible for colitis in six group I patients and five in group II, compared with three and five patients, resp., for the lincomycin-clindamycin class. Patients with PC were more seriously ill than those with NPC, and their disease lasted longer (31 versus 15 days, $p<0.01$). PC patients had more frequent abdominal distention ($p<0.001$), a faster pulse rate ($p<0.05$), and a higher temperature ($p<0.001$) or one of longer duration ($p<0.001$). The WBC count was higher in PC patients ($p<0.005$), and values for serum protein ($p<0.001$), hemoglobin ($p<0.005$), potassium ($p<0.001$), sodium ($p<0.05$), and total carbon dioxide ($p<0.025$) were lower. Seven NPC patients had target lesions in the rectosigmoid mucosa. At follow-up endoscopy, pseudomembranes were not present even if the disease had not been of shorter duration ($p>0.05$) than that of the PC patients. Although NPC and PC have different clinico-pathological manifestations, they may be of identical etiology. It is concluded that use of the term lincomycin-clindamycin colitis is unjustified.

0441 INTRALUMINAL PRESSURE IN THE SIGMOID COLON. II. PATIENTS WITH SIGMOID DIVER-

TICULA AND RELATED CONDITIONS. (Eng.) Weinreich, J.; Andersen, D. (Surgical Univ. Clinic I, Aarhus Amtssygehus, DK-8000 Aarhus C, Denmark). *Scand. J. Gastroenterol.* 11(6):581-586; 1976.

Sigmoid pressure activity was measured in 188 patients with various colonic diseases to determine whether pathophysiological similarities exist in these entities. The clinical syndromes included chronic diverticular disease (62 patients), colonic diverticulosis (15), atypical diverticular disease (36), acute diverticular disease (26), colicky sigmoid syndrome (15), sigmoid syndrome with predominant diarrhea (8), sigmoid syndrome with predominant constipation (16), and sigmoid syndrome with vague dyspepsia (10). The last four groups refer to what is generally known as the irritable bowel syndrome. Intraluminal sigmoid pressure was determined after the administration of neostigmine (0.5 mg, i.v.). Analysis of variance indicated that patients with chronic diverticular disease, patients with acute diverticular disease, and patients with the colicky sigmoid syndrome all might belong to a single population with respect to pressure activity; the median motility indices in the three groups were 1,996, 1,469, and 1,815, resp. Patients in the other categories showed pressure activities similar to those previously reported in normal subjects.

LARGE INTESTINE

Ulcerative Colitis

0487 BLOOD pH: A TEST FOR ASSESSMENT OF SEVERITY IN PROCTOCOLITIS. (Eng.) Caprilla, R.; Vernia, P.; Colanieri, O.; Torsoli, A. (Policlinico Umberto I, Rome, Italy). *Gut* 17(10):763-769; 1976.

Clinical and laboratory studies on 58 patients with active idiopathic proctocolitis (complicated by toxic megacolon in 10 cases) are reported. As the severity and extent of disease increased, arterial pH became progressively higher. In cases of mild and moderate disease, mean pH values of about 7.43 and 7.42, resp., were observed; a pH over 7.50 invariably indicated severe colitis or toxic megacolon and usually corresponded with total colitis. Various degrees of correlation were found between pH and pulse rate (r=0.6036), body temperature (r=0.4806), ESR (r=0.4826), and plasma albumin (r=0.5778). In cases of mild, moderate, severe, and complicated (toxic megacolon) disease, the maximum body temperatures were 36.6 ± 0.07, 36.8 ± 0.16, 37.3 ± 0.15, and 37.6 ± 0.35 C, resp. The maximum pulse rates for the above disease categories were 78.8 ± 2.05, 82.7 ± 2.37, 93.8 ± 3.46, and 100.0 ± 6.6/min, resp. The ESR values (1st hr) for these disease categories were 9.08 ± 1.9, 30.3 ± 9.4, 27.7 ± 6.1, and 44.7 ± 9.0 mm, resp. Serum albumin levels for the disease categories were 3.75 ± 0.11, 3.23 ± 0.10, 2.57 ± 0.15, and 2.38 ± 0.22 g/100 ml, resp. A correlation was also found between arterial pH and gas in the small and large bowel ($r=0.5652$). Intestinal gas levels in mild, moderate, severe, and complicated disease were 54.4 ± 4.81, 75.1 ± 6.93, 139.3 ± 18.5, and 339.3 ± 27.8 cm^2, resp. Blood pH measurement and plain x-ray films of the abdomen are the most reliable single methods for rapid detection of the early phases of intestinal dilatation. A progressively increasing amount of intestinal gas and a blood pH above 7.50 should be regarded as alarm signs that toxic dilatation of the colon is impending.

0488 RISK FACTORS IN ULCERATIVE COLITIS.

(Eng.) Gilat, T.; Lilos, P.; Benaroya, P.; Zemishlany, Z.; Ribak, J. (Tel Aviv Univ. Sackler Sch. Medicine, Tel Aviv, Israel). *Digestion* 14(5/6):400-408; 1976.

Risk factors were analyzed in 504 Jewish patients with ulcerative colitis (UC). The incidences of severe attacks, weight loss, iron deficiency, liver disease, and arthritis were significantly ($p<0.05$) higher in women (27.0, 33.3, 32.4, 4.9, and 7.4%, resp.) than in men (16.5, 27.3, 25.4, 1.5, 2.3%, resp.). The severity of several parameters of UC tended to be in the following order by community group: Ashkenazi>Sephardi>Oriental. Mortality ($p<0.001$), weight loss ($p=0.05$), and duodenal ulcer ($p=0.01$) were significantly higher or more frequent in patients whose disease started after age 50 yr. Severe attacks were recorded in 25.1% of cases with definite UC and in 5.5% with probable UC ($p<0.001$). In definite UC, the extent of colon affected was distal in 31.6%, substantial in 41.1%, and universal in 16.2% (uncertain in 11.1%) of the cases; the corresponding incidences of extent in probable UC were 53.1, 22.4, and 2.2% (uncertain, 22.3%), resp. ($p<0.001$). Toxic megacolon and perforation occurred more frequently with increasing disease extent, but the small numbers involved were unsuitable for statistical analysis. Colectomy and mortality were significantly ($p<0.001$) more frequent with increasing disease extent; the incidence of colectomy in universal disease cases was 20.3% versus 6.2% for all cases, and the mortality incidence in universal disease was 24.6% versus 10.7% for all cases. Incidence of severe attacks was positively related to disease extent ($p<0.001$), with the incidences for uncertain disease extent and all cases being 16.7% and 21.6%, resp. The course of the disease was correlated positively with extent of colon affected ($p<0.001$). Other positive correlations found were length of follow-up and disease extent ($p<0.001$) and length of follow-up and disease severity ($p<0.05$).

0489 ULCERATIVE COLITIS IN CHILDREN: RESULTS OF COLECTOMY IN 38 PATIENTS WITH CHILDHOOD ONSET OF DISEASE.

(Eng.) Naas, R.; Gruner, O. P. N.; Flatmark, A.; Fretheim, B.; Gjone, E. (Rikshospitalet, Oslo, Norway). *Z. Kinderchir.* 21(3):237-244; 1977.

Ulcerative colitis was studied in children (38 colectomized patients) using ileostomy (14 patients) and ileorectal anastomosis (IRA, 24 patients). A majority of the children were growth retarded at the time of operation. Only 6 of the 38 children had fulminating disease. Duration of the disease before operation was an average of 5.7 yr. The follow-up period (range 18 months-14 yr) ended at the age of 21 yr. Colectomy as late as 16 yr of age had a positive effect on stature ($p<0.01$). Cancer occurred in four IRA patients and appears to be a much greater risk in patients with childhood onset of the disease. Only 6 of the 20 survivors obtained a satisfactory bowel function. Relaparotomy was necessary in 13 of the IRA patients but in none of the ileostomy patients. Ileostomy is a safer operation than IRA and has a significantly lower frequency of complications ($p=0.005$) leading to relaparotomy. Hence, 17 of the 24 IRA patients were either dead, converted to ileostomy, or had an unsatisfactory functional result. Ileostomy function, measured as the interval between changing of the bag, was 1-7 days. Ileostomy function was better ($p=0.0004$) in young patients than in patients after puberty. All survivors except one were able to work, and six of them married. Young patients with ileostomy adapted well and were reported to have fewer problems in their daily life than patients with later onset of disease. Therefore, young age is not a contraindiaction for proctocolectomy and ileostomy.

0490 GLUCOSAMINE SYNTHETASE ACTIVITY OF THE COLONIC MUCOSA IN ULCERATIVE COLITIS AND CROHN'S DISEASE.

(Eng.) Goodman, M. J.; Kent, P. W.; Truelove, S. C. (Dept. Medicine, Univ. Chicago, IL). *Gut* 18(3):219-228; 1977.

A miniaturizing method for assay of glucosamine synthetase (GS), requiring just over 4 mg of tissue obtained by rectal biopsies, is described. The study was undertaken to identify differences in GS levels between ulcerative colitis (UC) and Crohn's disease (CD). The mean levels of GS in normal human colonic mucosa (25 colectomy specimens and 20 rectal biopsies) were 13.77 ± 3.97 μmol glucosamine synthesized/hr/g wet weight. There was a lower mean of GS levels in the colectomy specimens from patients with UC and CD, which was related to diminution in the epithelial cell density. However, in samples of mucosa in which the epithelial cells were absent, the GS levels were 3.0 ± 0.9 μmol/hr/g. GS levels were normal when there was loss of goblet cells only. In 15 of the 20 patients recovering from an acute attack of UC, the GS level rose to a peak above the normal range (mean peak level 23.94 μmol/hr/g) followed by a fall to within normal range. This effect did not occur in five patients who did not make prompt recovery. The GS levels in 13 biopsies from patients with CD sparing rectum had a mean of 20.55 μmol/hr/g, considerably higher than that of the normal range ($p<0.001$). The peak effect in UC appears to be a manifestation of recovery and probably is related to the synthesis of gastrointestinal mucus or immunoglobulin or the secretory component of IgA, all of which contain large amounts of *N*-acetyl-glucosamine.

PANCREAS

0504 CHYMOTRYPSIN OUTPUT IN THE STOOLS IN PANCREATIC AND OTHER DISEASES. (Eng.) Gilat, T.; Gelman-Malachi, E.; Ronen, O. (Ichilov Hosp., Weizman St., Tel Aviv, Israel). *Am. J. Gastroenterol.* 66(2):140-145; 1976.

The value of a method in which chymotrypsin output in the stools is calculated from analysis of single stool samples, using cuprous isothiocyanate as a continuous marker, was assessed in 16 patients with and 45 patients without pancreatic disease. The calculated values agreed favorably with those from 3-day stool collections. In 45 controls, with and without steatorrhea, the chymotrypsin output was above 10,000 U/24 hr. In six patients with pancreatic insufficiency, the values were considerably lower; all were below 4,000 U/24 hr. In 10 patients with pancreatic disease without insufficiency, the values were in the normal range (>10,000 U/24 hr). This method appears to be very useful in the diagnosis of pancreatic insufficiency, but it is not sensitive enough to detect lesser degrees of pancreatic damage.

PANCREAS

Pancreatitis

0515 A NEW PATTERN OF PANCREATIC SECRETION (PBS) OBSERVED IN PANCREATIC EDEMA. (Eng.) Tuzhilin, S. A.; Dreiling, D. A. (Mt. Sinai Medical Sch., City Univ. New York, 100th St. and Fifth Ave., New York, NY 10029). *Am. J. Gastroenterol.* 67(3):220-228; 1977.

Exocrine pancreatic secretion studies were done on 53 patients with pancreatic edema and 3 Thomas cannula dogs to elucidate the pathogenesis of proximal block of pancreatic secretion (P.B.S.). Pancreatic secretion was investigated using secretin and intraduodenal HCl as stimuli. An abnormal pattern of secretion following HCl administration in pancreatic edema patients (20) was observed: there was a significant decrease in flow ($p<0.001$), decreased bicarbonate concentration ($p<0.05$ after 20- to 40-min stimulation), and increased amylase concentration ($p<0.01-0.05$). Reversal of the secretory pattern after i.v. secretin administration (1 clinical U/kg) towards normal for flow and bicarbonate concentration was seen, though the hyperconcentration of the enzyme ($p<0.01-0.001$) compared to the normal patients (13) persisted. Comparison of the weak HCl and strong secretin stimulus to pancreatic secretion in the pancreatic edema patients augmented the abnormal discordant secretory defect (diminuition in flow, $p<0.001$); there was an insignificant effect on bicarbonate concentration and an insignificant increase in amylase concentration. This reversal of the secretory pattern of P.B.S. is due to a larger secretory flow nullifying the dilution effect of interstitial fluid exudation into the duct system. Dehydration with diuretics in pancreatic edema patients (14) reversed the secretory abnormality (P.B.S.). Secretin test response in dogs before and after adrenalin infusion (0.1-1%) showed decreased flow (p<0.001->0.10) and increased enzyme concentration (p<0.01). The combined low stimulus-high stimulus approach is suggested to study pancreatic damage or dysfunction.

0516 ENDOSCOPIC RETROGRADE PANCREATOGRAPHY AND SECRETIN-PANCREOZYMIN TEST IN DIAGNOSIS OF CHRONIC PANCREATITIS: A COMPARATIVE EVALUATION.

(Eng.) Dobrilla, G.; Fratton, A.; Valentini, M.; Vantini, I.; Cavallini, G.; Angelini, G.; *et al.* (Ospedale Generale Regionale, I-39100 Bolzano, Italy). *Endoscopy* 8(3):118-123; 1976.

The diagnostic values of endoscopic retrograde pancreatography (ERP) and secretin-pancreozymin (S-CCK.PZ) test were compared in 23 patients, 6 with suspected chronic pancreatitis and 17 with proven chronic pancreatitis. The results showed a good correlation between ERP examinations and S-CCK.PZ test only for patients with proven chronic pancreatitis. In patients with suspected chronic pancreatitis, there were discrepancies between ERP (normal results) and S-CCK.PZ test (abnormal for the only parameter "low flow"). The principal types of ERP abnormality were alternate dilatation and stenosis of Wirsung's duct (75%), cystic dilatation of branches (58%), irregular distribution of the branches (41%), and calculi in Wirsung's duct (34%). The time of elimination of the contrast medium was significantly correlated with the S-CCK.PZ test and with the pancreatographic picture.

0517 ULTRASOUND IN THE MANAGEMENT OF ACUTE PANCREATITIS.

(Eng.) Duncan, J. G.; Imrie, C. W.; Blumgart, L. H. (Royal Infirmary, Glasgow, G40SF, Scotland). *Br. J. Radiol.* 49(586):858-862; 1976.

Following a proven attack of acute pancreatitis, 38 patients were referred for ultrasound examination when signs or symptoms suggested the development of a pancreatic pseudocyst. Pseudocysts were diagnosed by ultrasound in 23 cases (12 related to alcohol, 6 to biliary disease, 2 to trauma, and 3 to other causes). Five patients had multilocular cysts, four of which were shown by ultrasound to be communicating. Pseudocyst was confirmed in 13 of 14 patients undergoing laparotomy, and surgical drainage was performed in 12 of these patients. Three patients had small cysts (less than 6 cm in diameter) in the head of the pancreas; two were proven at laparotomy and were successfully treated by surgical drainage. The remaining nine cases (8 single cysts and 1 multiple cyst) were monitored over periods of 4-12 weeks and showed spontaneous regression. An area of irregular absorption of ultrasound in 12 additional patients among the 38 examined was interpreted as an inflammatory mass that was confirmed in all 3 cases requiring laparotomy. Serial scanning of these 12 patients showed resolution of the mass over periods of 4-20 weeks. None of these cases developed a pseudocyst, but three required operation, one for an abscess, one for necrosis of the body and tail of the pancreas, and a third for severe pancreatic fibrosis. Three of the 38 patients examined showed no ultrasound evidence of inflammatory mass or cyst, and these 3 improved spontaneously without surgery. Ultrasonic scanning is a useful noninvasive means for distinguishing between pseudocysts and inflammatory masses and for demonstrating communication between multiple cysts.

0518 CALCIFIC PANCREATITIS AND IMMUNOLOGY.

(Ger.) Klemm, G.; Rohde, L. (Abteilung fur Poliklinische Diagnostik, Wilhelm-Pieck-Universitat Rostock, Ernst-Heydemann-Str., DDR-25 Rostock, E. Germany). *Dtsch. Z. Verdau. Stoffwechselkr.* 36(2):73-75; 1976.

No change in plasma amylase levels was noted in 24 rats with chronic interstitial calcifying pancreatitis induced by vitamin D_2 (1 mg/100 g, s.c.) and iron dextran (0.3 ml in the pancreatic stroma). Eight animals died of calcifying pancreatitis within 3 months, and body weight decreased on the average by one-third during the first test week. Histologically, chronic granulating inflammation with foreign giant cells as well as pseudoductular parenchyma regeneration were found in the interstitial calcification. Other test results have shown that not only a macromolecule, such as iron dextran, but also isolated rat peritoneal mast cells with IgE can cause degranulation. In calcifying pancreatitis, a mast cell reaction induced by an immune mechanism reaction may be possible.

0519 STUDIES ON SERUM AMYLASE IN NORMAL MAN AND IN ACUTE PANCREATITIS.

(Eng.) MacGregor, I. L.; Zakim, D. (Veterans Admin. Hosp., 4150 Clement St., San Francisco, CA 94121). *Aust. N.Z. J. Med.* 6(6):551-556; 1976.

To assess the potential significance of amylase isoenzymes in the diagnosis of pancreatic disease, amylase isoenzyme patterns were determined in human serum, urine, saliva, jejunal juice, and pancreatic tissue. The isoenzymes were separated by isoelectric focusing. The predominant amylase isoenzyme fraction in 11 of 14 samples of autopsy pancreases focused with an isoelectric point between 6.8 and 7.1. The crude homogenate of all such glands that were tested had the ability to hydrolyze *p*-tosyl arginine methyl ester hydrochloride (TAME). TAME esterase activity was not detectable in the crude homogenates of three pancreases with isoamylases focusing with isoelectric points between 6.2 and 6.3, although a number of glands without detectable TAME esterase activity contained isoamylases focusing predominantly at pH 6.8 to 7.1. The amylase isoenzymes in freshly expectorated saliva showed two major isoenzyme peaks with isoelectric points between 5.8 to 6.0, and 6.3 to 6.4. Amylase isoenzymes in aspirates from the small intestine demonstrated isoenzymes derived from the pancreas and salivary glands. The pattern of isoenzymes of amylase in the sera of normal subjects revealed fractions likely to be derived from the salivary glands and the pancreas. In the majority of sera, the major amylase isoenzyme had an isoelectric point between 5.8 and 6.0. This peak coincided with the major peak from saliva, and was therefore of salivary gland origin. The pattern of isoenzymes in sera and urine from patients with acute pancreatitis differed quantitatively from that in normal subjects. The predominant peak of amylase activity in acute pancreatitis sera had an isoelectric point of 6.8 to 7.1. The activity of the amylase isoenzymes of presumed salivary origin was also increased. The mean renal clearance of amylase as the percentage of creatinine clearance in four patients with acute pancreatitis was 4.7 ± 1.2. The clearance of the pancreatic peak with an isoelectric point of 6.8 to 7.0 was 7.1 ± 3.5%, and the clearance of the salivary peak with an isoelectric point between 5.8 and 6.0 was 3.0 ± 1.1%. The increased renal clearance of amylase in acute pancreatitis may be due partly to the increased proportion of the smaller molecular weight pancreatic amylase. However, the increase in the renal clearance of salivary amylase suggests that the kidneys are also involved. These studies also indicate that the majority of amylase activity in normal sera is of salivary gland origin.

0520 POSSIBLE MECHANISMS OF NORMAL AMYLASE ACTIVITY IN HYPERLIPEMIC PANCREATITIS. (Eng.) Mishkin, S.; Bates, J.; O'Hashi, J.; Schneider, P.; Sniderman, A. D.; Wolf, R. O. (Royal Victoria Hosp., 687 Pine Ave. W, Montreal, Quebec H3A 1A1, Canada). *Can. Med. Assoc. J.* 115(10): 1016-1019; 1976.

Possible mechanisms of normal amylase activity in patients with hyperlipemic pancreatitis were investigated. When lipemic serum from three patients with acute pancreatitis and type IV hyperlipemia was fractionated into very-low-density lipoproteins (VLDL) and clear serum amylase activities (determined by the Phadebas method) in the VLDL fractions (20, 40, and 384 IU/l, resp.) and clear serum fractions (67, 157, and 525 IU/l, resp.) never exceeded the amylase activities in the original lipemic sera (165, 490, and 1,875 IU/l, resp.). This fact indicates that the removal of lipid turbidity from the original lipemic sera did not unmask high levels of amylase activity in the remaining clear serum. The addition of the VLDL and clear serum fractions or the addition of VLDL and chylomicrons from asymptomatic patients with hyperlipemia to nonlipemic serum from three patients with routine acute pancreatitis and high serum amylase activities (1000-6,000 IU/l) did not inhibit the amylase activities or alter the electrophoretic mobility of amylase isoenzymes. Therefore, the normal amylase activity often observed in hyperlipemic pancreatitis does not result from an inhibition of amylase activity by serum lipoproteins.

0521 POST-TRANSPLANTATION PANCREATITIS. (Eng.) Fernandez, J. A.: Rosenberg, J. C. (Dept. Surgery, Wayne State Univ., Detroit, MI). *Surg. Gynecol. Obstet.* 143(5):795-798; 1976.

A review of the literature on postrenal transplantation pancreatitis is presented along with case reports of two women developing this condition. Post-transplantation pancreatitis occurs with a frequency of about 3% and carries a mortality of 70%. An average of 216 days (range, 1-570 days) following transplantation elapses before the onset of pancreatitis, which occurs most frequently in men in the fourth decade of life. Post-transplantation pancreatitis was unsuspected in 35% of patients with this condition who died and were autopsied. Factors that predispose to pancreatitis in the post-transplant period include immunosuppressive therapy with azathioprine and steroids, secondary hyperparathyroidism, and increased susceptibility to infection. The diagnosis of pancreatitis depends greatly on an increase in the serum amylase level, which had been found to vary from 2 to 40 times the normal value in post-transplant patients with pancreatitis. In one of the two cases reported, the serum amylase level was 340 U/100 ml 3 months post-transplant, and a serum amylase level as high as 1,600 U/100 ml was recorded in the other patient 3.5 months after renal transplantation. After renal transplantation, patients should frequently have serum and urinary amylase determinations, with these determinations being compared to the creatinine clearance rates. The diagnosis of pancreatitis should be considered if any abdominal symptoms occur. It is possible that post-transplant pancreatitis is caused by a virus and is related to the immunosuppressive state. The presence of cytomegalovirus in the pancreas has been reported, but its pathogenetic significance is uncertain.

LIVER AND BILIARY TRACT

0534 LAPAROSCOPY WITH PARTICULAR REFERENCE TO MANAGEMENT OF DISEASES OF THE LIVER. (Eng.) Walker, R. J.; Williams, R. *In: Modern Topics in Gastrointestinal Endoscopy*. Edited by K. F. Schiller, and P. R. Salmon. (Chicago: William Heinemann Medical Books): 275-295; 1976.

In this review, laparoscopy is discussed in terms of equipment, technique, indications for use, results, and complications. The normal and pathological appearance of abdominal organs observed by laparoscopy is described. Biopsy is considered to be an essential part of the technique and should be performed, if possible, to confirm laparoscopic findings. The most common indications for the procedure are hepatomegaly, unexplained liver function test abnormalities, suspected cirrhosis or tumor, jaundice, and ascites. The correct diagnosis was made by laparoscopy in 75 of 100 consecutive patients examined for the aforementioned indications. Five case histories are presented to illustrate typical diagnostic situations in which laparoscopy proved to be valuable.

0535 DISPOSITION OF AMINOPYRINE, ANTIPYRINE, DIAZEPAM, AND INDOCYANINE GREEN IN PATIENTS WITH LIVER DISEASE OR ON ANTICONVULSANT DRUG THERAPY: DIAZEPAM BREATH TEST AND CORRELATIONS IN DRUG ELIMINATION. (Eng.) Hepner, G. W.; Vesell, E. S.; Lipton, A.; Harvey, H. A.; Wilkinson, G. R.; Schenker, S. (Harbor General Hosp., Torrance, CA 90509). *J. Lab. Clin. Med.* 90(3):440-456; 1977.

The extent of hepatic elimination of various drugs was compared in controls, patients receiving anticonvulsants that stimulate the microsomal oxidizing system, and patients with hepatobiliary diseases (hepatocellular disease, hepatic neoplasm, or cholestasis). Aminopyrine metabolism was measured by the aminopyrine breath test, diazepam elimination by a newly developed ^{14}C-diazepam breath test (DBT) and by conventional plasma diazepam measurements, antipyrine clearance by drug analysis in saliva, and indocyanine green (ICG) clearance by its removal rate from plasma. The DBT correlated well with diazepam half-life when all subject groups were combined ($r=-0.65$, $p<0.001$). Anticonvulsant drugs enhanced the elimination of aminopyrine, diazepam, and antipyrine, but the degree of stimulation was significantly lower for aminopyrine; ICG elimination was not altered by anticonvulsant drugs. The mean elimination for each drug tested in patients with hepatocellular and neoplastic liver diseases was depressed significantly and to a similar extent. In cholestasis, elimination of antipyrine and ICG but not of aminopyrine or diazepam was depressed significantly. Finally, there was no consistent correlation of the elimination of the four drugs tested in controls alone, and the correlation, although sometimes statistically significant, was only marginal (r=0.30-0.67) in the combined hepatobiliary group alone. Attempts to extrapolate pharmacokinetic data from one drug to another in individual subjects may be misleading.

0536 GROWTH HORMONE AND PROLACTIN RESPONSES TO THYROTROPIN-RELEASING HORMONE IN PATIENTS WITH SEVERE LIVER DISEASE.

(Eng.) Panerai, A. E.; Salerno, F.; Manneschi, M.; Cocchi, D.; Muller, E. E. (Dept. Pharmacology, Univ. Milan, Milan 20129, Italy). *J. Clin. Endocrinol. Metab.* 45(1):134-140; 1977.

To determine whether abnormalities in growth hormone release (GH) in severe liver diseases are related to a positive GH response to thyrotropin-1 releasing hormone (TRH, 400 μg) was administered i.v. to 10 patients with severe liver disease and to 10 controls. TRH induced a clear-cut GH rise (≥10 ng/ml) in seven patients; this occurred 15-120 min after the injection. TRH had no effect on GH levels in controls. The mean baseline GH levels were higher in patients than in controls (3.8 ± 1.0 versus 0.8 ± 0.4 ng/ml, p<0.02). An exaggerated and sustained increase in prolactin (PRL) was present after TRH in the subjects with liver disease, whose mean baseline plasma PRL levels were within the normal range. Although the rise in GH induced by TRH may be due primarily to a disturbance in the neuroendocrine control of GH secretion, the exaggerated PRL rise after the tripeptide seems to be caused by peripheral factors.

0537 METHODS FOR DETECTION OF ANTI-ALBUMIN AUTOANTIBODIES IN HEPATIC DISEASES.

(Eng.) Lenkei, R.; Ghetie, V. (Dept. Immunology, Babes Inst., Bucharest 6, 76, 210, Rumania). *J. Immunol. Methods* 16(1):23-30; 1977.

The application of three methods for the detection and quantitation of anti-albumin autoantibodies (AAA) in human sera is described. The methods are based on their reaction with a new antigenic site of glutaraldehyde-polymerized human serum albumin (HSA). The first method is a double diffusion technique (ID-HSA) where the sera to be tested are reacted with a copolymer of glutaraldehyde activated HSA (copoly-HSA). The reaction is estimated by the lowest copoly-HSA concentration giving precipitation with the undiluted sera. The second method is based on agglutination (HA) by AAA-positive sera of human RBC coated with glutaraldehyde-polymerized HSA (EPA). The reaction is quantified as the highest dilution of sera giving agglutination. The third method uses glutaraldehyde-insolubilized HSA as an immunoabsorbent able to bind AAA in positive sera. The quantity of protein absorbed, expressed in μg antibody/ml serum, measures the level of AAA in sera. Glutaraldehyde treatment of HSA led to the formation of soluble polymers that were able to react strongly in immunodiffusion with patients' reference sera. The HSA polymers responsible for this reaction could be prepared in high yield; more than 85% of the treated HSA was polymerized. At pH 9.0, glutaraldehyde-activated HSA bound a further amount of nontreated HSA yielding copoly-HSA. The correlation between the immunodiffusion test with animal sera (ID-AS) and ID-HSA was investigated in sera from 86 patients with acute viral hepatitis, 97 blood donors, and 84 contacts for hepatitis B surface antigen. Agreement between results occurred in 89.6% of the sera from the hepatitis patients, 84.2% of the sera from blood donors, and 91.3% of the sera of the hepatitis contacts. HA-EPA tests in the sera of healthy donors and patients with liver diseases showed that titers up to 1:32 did not indicate liver dysfunction. Titers of 1:64 to 1:4,096 were recorded in the sera of patients with liver disease and were significantly correlated with positive ID-HSA tests in viral hepatitis and in HBsAg contacts. The immunoabsorbent technique permitted the estimation of AAA concentrations in normal and pathological sera. Generally, a lack of reaction with copoly-HSA in immunodiffusion was associated with an AAA concentration below 100 μg/ml, while higher concentrations of AAA (>200 μg/ml) were associated with precipitation of copoly-HSA at 39-625 μg/ml. Highly significant correlation coefficients were calculated between the immunoabsorbent technique, ID-HSA, and HA-EPA techniques.

0538 SERUM IMMUNOGLOBULINS AND ORGAN NON-SPECIFIC ANTIBODIES IN DISEASES OF THE LIVER.

(Eng.) Husby, G.; Skrede, S.; Blomhoff, J. P.; Jacobsen, C. D.; Berg, K.; Gjone, E. (Rikshospitalet, Oslo 1, Norway). *Scand. J. Gastroenterol.* 12(3):297-304; 1977.

Serum immunoglobulins and complement fraction 3 (C3) levels, rheumatoid factors (RF), hepatitis B surface antigen (HB antigen) and antibody (HB antibody), and auto-antibodies to smooth muscle (SMA), mitochondria (MA), and nuclei (ANA) were determined in 202 patients with one of nine liver diseases. Hypergammaglobulinemia was a prominent feature in most groups, IgG being particularly raised in active chronic hepatitis, IgM in primary biliary cirrhosis, and IgA in alcoholic liver disease, resp. IgE was often increased in alcoholic liver disease and was frequently low in hepatic tumors, whereas IgD showed no typical pattern in any liver disorder. SMA was most frequently found in active chronic hepatitis (68%), and MA in primary biliary cirrhosis (58%), while ANA was detected in 50% of the patients with active chronic hepatitis. However, a pronounced over-lap of tissue antibodies was observed among the various groups of liver disease, particularly in active chronic hepatitis and primary biliary cirrhosis. The concurrent presence of SMA and ANA was most frequent in active chronic hepatitis. Antibody titers might have provided better diagnostic discrimination, since titration of antibodies was not performed. Low C3 levels in active chronic hepatitis were correlated with low levels of other liver synthesized proteins, and no evidence was found on increased consumption by immunologic reactions.

0539 THE ASSOCIATION OF FAMILIAL LIVER DISEASE, SUBEPIDERMAL IMMUNOPROTEINS, AND MEMBRANOPROLIFERATIVE GLOMERULONEPHRITIS.

(Eng.) Dobrin, R. S.; Hoyer, J. R.; Nevins, T. E.; Sharp, H.; Gentry, W. C.; Vernier, R. L. (Children's Hosp. Medical Center of Northern California, 51 and Grove St., Oakland, CA 94609). *J. Pediatr.* 90 (6):901-909; 1977.

A new form of congenital hepatic disease is reported. Each of the four siblings had splenomegaly, hypersplenism, a small liver, biochemical evidence of hepatic excretory dysfunction and hepatocellular damage, kidneys without demonstrable cysts, and normal blood pressure. An evaluation of serum immunoproteins, autoantibodies, histocompatibility antigens, and mixed lymphocyte reactivity further defined the immunologic features of this syndrome. Extrahepatic manifestations included a papulosquamous dermatitis with deposition of immunoglobulins and complement in both normal and abnormal skin; a membranoproliferative glomerulonephritis with subendothelial deposits; arthritis; and pericardial, pleural, and synovial effusions. Further evaluation of this family is required to better understand the pathogenesis of this disease.

0540 CRYPTOGENIC LIVER ABSCESS.

(Ger.) Gunther, B.; Gruner, A.; Bull, U. (Chirurgische Klinik der Universitat, Nussbaumstrasse 20, D-8000 Munich 2, W. Germany). *Munch. Med. Wochenschr.* 119(9):305-308; 1977.

Cryptogenic liver abscess was diagnosed in a 61-yr-old woman and a 50-yr-old man by liver scintigraphy and celiacography (in one case). Both patients had fever and were in severely impaired general condition, but there were no pathognomonic symptoms. After aspiration of the purulent liquid, transperitoneal drainage was applied. The cavity was irrigated daily with saline solution containing antibiotics and enzyme preparations. The treatment was successful, both patients were in good condition at discharge and at the follow-up several months later, at which time no filling defects were seen in the liver scintigraphically. The findings indicate that transperitoneal open drainage is the method of choice in the treatment of patients with cryptogenic liver abscess.

0541 PROGNOSIS OF HEPATOPATHY IN HOMOZYGOUS ALPHA-1-ANTITRYPSIN DEFICIENCY.

(Ger.) Karitzky, D.; Kunzer, W. (Universitats-Kinderklinik, D-7600 Freiburg i. Br., W. Germany). *Monatsschr. Kinderheilkd.* 125(5):472-473; 1977.

The prognosis of children with hepatopathy with homozygous alpha$_1$-antitrypsin deficiency (aATD) of the protease inhibitor type ZZ is discussed on the basis of the observation of 10 cases. The aATD was detected at the age of 3-8 weeks in connection with jaundice, hepatomegaly, or dystrophy in five cases, and serendipitously in five others. In the latter group, only one child developed progressive liver cirrhosis. In four of the other five patients, in whom aATD was diagnosed at an early age in connection with liver cirrhosis, bile duct hypoplasia, infectious hepatitis, or liver fibrosis, the initially highly elevated transaminase levels and other clinical findings normalized during the follow-up period (6-15 yr). The aATD was subject to fluctuations, and its increase was accompanied by the normalization of the transaminase level. The findings indicate that the normalization of the transaminase levels by the age of 3-5 yr is prognostically favorable, and that the frequency of juvenile cirrhosis in children with aATD is lower than the 20-30% it is generally believed to be. Persons with homozygous aATD are not overrepresented among patients with liver cirrhosis.

0542 ALPHA-FETOPROTEIN AND THE DIAGNOSIS OF LIVER CELL CANCER.

(Eng.) Purves, L. R. *In: Liver Cell Cancer.* Edited by H. M. Cameron, D. A. Linsell, and G. P. Warwick. (New York: Elsevier Scientific Publishing Company): 61-79; 1976.

The physiology of alpha fetoprotein (AFP) is described, and its use in screening for liver cell carcinoma is reviewed. The use of AFP in the diagnosis of liver cell cancer is invaluable; most cases can be accurately diagnosed or justification can be provided to pursue the diagnosis by other means. Whether the measurement of AFP is justified as an epidemiological tool is doubtful, since there is a normal AFP level (the effects of subclinical hepatitis altered this normal level) and since liver cell cancer is, in general, not responsive to treatment. Further prospective surveys using radioimmunoassay for the quantitation of AFP are necessary before it can be used to detect evolving cancer at an early enough stage to be beneficial to the patient.

0543 THERAPEUTIC INDICATIONS FOR CHILDREN WITH PRIMARY LIVER TUMORS.

(Fre.) Mitrofanoff, P. (No affiliation given). *Ann. Chir. Infant.* 17(5/6):479-483; 1976.

The types of therapy for children with primary liver tumors are reviewed. Surgery (tentative hepatectomy) is recommended for malignant tumors, as radiotherapy or chemotherapy is not very successful. However, radiotherapy (up to 1,000 rads) is indicated for stopping the involution of angioma, and, in serious cases, ligature of the hepatic artery has been effective. Corticotherapy has also been used for fast-growing angiomas. Surgery has been used for cystic lymphangiomas. Angiomas usually occur in the first 3 months of life, but malignant tumors usually develop later. Malignancies can be detected by clinical and biological tests and radiological vascular exploration. Determination of α-fetoprotein levels is especially useful in distinguishing between angiomas and hamartomas in young infants. Surgery for angioma has proved fatal in some cases: 6/17 children died after excision, but 3/3 given radiotherapy were cured. A review of 81 children with malignant tumors (hepatoblastoma/hepatocarcinomas and sarcoma) showed that 68 had died, compared to 89/155 with benign tumors (angioma and hamartoma).

0544 THE TREATMENT OF LIVER CELL CANCER. (Eng.) Falkson, G. *In: Liver Cell Cancer.* Edited by H. M. Cameron, D. A. Linsell, and G. P. Warwick. (New York: Elsevier Scientific Publishing Company): 81-92; 1976.

Surgery, radiotherapy, and chemotherapy of liver cell cancer are reviewed. Primary liver cell cancer is seldom resectable, and is not radiosensitive. Clinical control must be sought by chemotherapy. 5-Fluorouracil given intravenously has been generally accepted in the U.S.A., but worthwhile responses have not followed extensive clinical trial of this agent in Bantu patients. Alkylating agents, antimetabolites, antibiotics, and other drugs have been carefully evaluated in patients with liver cell cancer and have been found not to be of particular value. Recent advances in chemotherapy make it more likely that treatment with cytostatic agents will lead to better results.

0545 A PHASE II STUDY OF ADRIAMYCIN (NSC 123127) IN PATIENTS WITH HEPATOCELLULAR CARCINOMA FROM ZAMBIA AND THE UNITED STATES. (Eng.) Vogel, C. L.; Bayley, A. C.; Brooker, R. J.; Anthony, P. P.; Ziegler, J. L. (Univ. Miami, Sch. Medicine, 1400 N.W. 10th Ave., Center House--Roof Garden, Miami, FL 33136). *Cancer* 39(5):1923-1929; 1977.

Nineteen Zambian and 22 American patients with hepatocellular carcinoma were treated with adriamycin (ADM; 20-75 mg/m^2, i.v, depending on the initial serum bilirubin level) every 3 weeks. Four of 16 "good risk" Zambian and American patients (those eligible for 75 mg of drug) had objective responses, while in 5 others there was evidence of either transient tumor regression or disease stabilization; only 3 of 25 "poor risk" patients who received 20-60 mg/m^2 had objective responses. Even in this latter group, however, transient objective signs of tumor regression were noted in four patients. Toxicity at 75 mg/m^2 was more profound than with lower doses but was tolerable and reversible. It is concluded that ADM does yield reproducible and objective antitumor responses in hepatocellular carcinoma and that it is worthy of further investigation.

0546 5-FLUOROURACIL IN HEPATOCELLULAR CARCINOMA: REPORT OF TWENTY-ONE CASES. (Eng.) Link, J. S.; Bateman, J. R.; Paroly, W. S.; Durkin, W. J.; Peters, R. L. (Univ. Southern California Sch. Medicine, LAC-USC-MC, 1200 N. State St., Los Angeles, CA 90033). *Cancer* 39(5):1936-1939; 1977.

Twenty-one patients with biopsy-proven hepatocellular carcinoma were treated with oral (group 1) or intravenous (group 2) 5-fluorouracil (15 mg/kg/week for a period of 6 weeks) according to a randomized treatment schedule. There were no objective responses in either treatment group. One patient on oral therapy showed a transient 25% tumor reduction, and another patient showed stable disease for 12 weeks after the beginning of the therapy. Overall response in the study was zero percent, but two patients did receive marginal therapeutic benefit. The median survival for the group was 65 days. The median survival for orally treated patients was 72 days compared to 45 days for the group treated with intravenous 5-fluorouracil ($p<0.20$). Toxicity occurred in 46% of patients treated, but was tolerable; mild gastrointestinal toxicity was the most commonly noted form, occurring in 30% of patients. Marrow suppression occurred in 18%, but with no severe episodes. It is suggested that weekly oral or intravenous 5-fluorouracil administration has a minimal role in the treatment of hepatocellular carcinoma.

0547 THE GEOGRAPHIC PATHOLOGY OF LIVER CELL CANCER. (Eng.) Linsell, D. A.; Higginson, J. *In: Liver Cell Cancer.* Edited by H. M. Cameron, D. A. Linsell, and G. P. Warwick. (New York: Elsevier Scientific Publishing Company): 1-16; 1976.

The frequency and types of liver cancers observed in different areas of the world are reviewed. Liver cancer remains a major problem of many areas of the developing world and is probably one of the most frequent cancers in man. Although there is some evidence that the incidence may be falling in Africa, there are reports of a higher incidence in Europe. The association of the cancer with cirrhosis is well established, but the precise sequence of events is still unclear. One type of cirrhosis, the macronodular, is more frequently associated with the cancer, and this is the cirrhosis most commonly observed in countries reporting high frequencies of liver cell cancer. It is now possible to evaluate some of the environmental factors, both viral and chemical, that may be involved in this entity's increased frequency.

0548 THE CLINICAL PROBLEM OF LIVER CELL CANCER IN A HIGH INCIDENCE AREA. (Eng.) Bagshawe, A.; Cameron, H. M. *In: Liver Cell Cancer.* Edited by H. M. Cameron, D. A. Linsell, and G. P. Warwick. (New York: Elsevier Scientific Publishing Company): 45-59; 1976.

The clinical features of liver cell cancer in developing countries are described and compared with those seen in Europe and America. In the latter countries, it affects older people, is often superimposed on recognized cirrhosis, and produces a less dramatic illness. The disease must be distinguished from liver abscess, parasitic liver diseases, and cirrhosis, as well as from secondary liver tumors; the last are relatively infrequent in most areas with a high incidence of liver cell cancer. Final proof of the diagnosis rests on the histology of the tumor, but the elevation of serum alpha fetoprotein to a level detectable by immunodiffusion is seldom seen, except in the liver cell cancer, pregnancy, and certain teratomas. More sensitive methods of measuring alpha fetoprotein may give false positive results. Hepatic scintigraphy and angiography allow accurate tumor localization for biopsy and will determine its extent and vascularization if surgical resection or intraarterial perfusion of chemotherapeutic agents is planned. However, the results of chemotherapy are so poor that there is seldom justification for subjecting patients to the toxicity of conventional cytotoxic drugs; management usually consists of the relief of pain and sympathetic terminal care.

0549 THE BACKGROUND TO LIVER CELL CANCER. (Eng.) Anthony, P. P. *In: Liver Cell Cancer*. Edited by H. M. Cameron, D. A. Linsell, and G. P. Warwick. (New York: Elsevier Scientific Publishing Company): 93-120; 1976.

Liver diseases, occurring in geographical areas where hepatocellular carcinoma is common, and factors thought to be involved in the genesis of cirrhosis are reviewed. Liver cell cancer occurs most frequently in cirrhotic liver, and it seems that almost any disease process that causes cirrhosis is associated with an increased risk of malignancy. The magnitude of this risk varies throughout the world, and it may be determined by differences in etiology. Race, sex, and genetics have little role to play. Alcoholism and, possibly, malnutrition have a potentiating influence, the nature of which is unclear. Parasites are not related to liver cell carcinoma, but infestation with various flukes, notably *Clonorchis sinesis*, is associated with a high incidence of intrahepatic bile duct carcinoma in South East Asia. Naturally occurring carcinogens, particularly aflatoxins, and the hepatitis B virus may be responsible for the majority of liver cell carcinoma in the tropics and subtropics. Liver cell cancer, in all its forms, remains a relatively rare disease in western countries, but its incidence is slowly rising and may be further increased by newly discovered, though yet unproven, carcinogens such as gonadal steroids and vinyl chloride monomer.

0550 PRIMARY HEPATOCELLULAR CARCINOMA--A RESUME. (Eng.) Rubin, E. *In: Liver Cell Cancer*. Edited by H. M. Cameron, D. A. Linsell, and G. P. Warwick. (New York: Elsevier Scientific Publishing Company): 279-286; 1976.

Factors involved in the study of hepatocellular carcinoma are reviewed. The origin and nature of primary hepatocellular carcinoma remains an enigma, but a number of factors render the tumor an excellent model for the study of neoplasms. These include world-wide incidence, geographic distribution, putative association with toxins, the high incidence of production of embryonal proteins, and the ease of production of the cancer in experimental animals. The challenges for the future include a better understanding of the reasons underlying the geographic distribution, the relationship of tumor development to cirrhosis and hyperplastic nodules, the multicentric nature of the tumor, the induction of tumors by chemicals in experimental animals and modifying factors, and the immunologic aspects of primary hepatic carcinoma.

0551 EARLY LESIONS AND DEVELOPMENT OF PRIMARY HEPATOCELLULAR CARCINOMA IN MAN--ASSOCIATION WITH HEPATITIS B VIRAL INFECTION. (Eng.) Okita, K.; Kodama, T.; Harada, T.; Noda, K.; Fukumoto, Y.; Takenami, T.; *et al.* (Yamaguchi Univ., Sch. Medicine, Ube City, Yamaguchi Prefecture 755, Japan). *Gastroenterol. Jpn.* 12(2):51-57; 1977.

Serum and liver biopsy specimens from 103 patients with chronic liver disease were examined for an association between serum α-fetoprotein (AFP) and liver cell dysplasia, which is postulated to be a precursor of primary hepatocellular carcinoma. Among 58 cases of chronic active hepatitis, 14 showed liver cell dysplasia, and 71.4% of these 14 cases had a serum AFP level of >200 ng/ml. Of the remaining 44 cases, 43.1% had a serum AFP level of >200 ng/ml. Liver cell dysplasia was also seen in 13/55 cases of liver cirrhosis, and 69.2% of these 13 cases had a serum AFP level of >200 ng/ml; this level was found in only 30.9% of the remaining 42 cases. Direct fluorescence antibody studies of 20 patients with high serum AFP levels indicated a specific localization of AFP in the dysplastic cells. Hepatitis B-associated DNA polymerase assays revealed a significantly high level of DNA polymerase activity (mean, about 1,800 counts/min) in the sera of patients with chronic active hepatitis, compared with a background level of 900 counts/min for normal subjects.

0552 TREATMENT OF VARIOUS FORMS OF ICTERUS OR CHOLESTASIS WITH PHENOBARBITAL. (Ger.) Stiehl, A. (Med. Univ.-Klinik Heidelberg, Bergheimer Strasse 59, 6900 Heidelberg, W. Germany). *Z. Gastroenterol.* 15(6):404-416; 1977.

The results of the treatment of various forms of icterus or cholestasis with phenobarbital (PB) are reviewed. In the liver, PB induces an increase in the endoplasmic reticulum, an increase of cytoplasmic proteins, and induction of microsomal enzymes such as bilirubin (BL) glucuronyl transferase, which catalyzes the conjugation of BL. PB also increases bile flow, and it improves BL conjugation in patients with Crigler-Najjar syndrome, Gilbert-Meulengracht disease, or newborn icterus. In patients with insufficient BL excretion, such as those with Dubin-Johnson disease, PB caused a decrease in serum BL levels by increasing biliary BL excretion. In cholestasis, PB caused an increase in biliary excretion of bile-binding substances, leading to a decrease in icterus, pruritus, and hyperlipemia. Daily therapy with PB (120-300 mg) improved icterus and pruritus in the majority of patients, but it was discontinued in some due to heavy sedation. In addition to improving icterus and pruritus, PB has also been observed to produce a marked improvement in the plasma clearance of rose bengal and cholestyramine. Side-effects attributed to PB include a rise in alkaline phosphatase activity and CNS and inflammatory symptoms in newborns.

0553 PURPURA CRYOMACROGLOBULINEMIA IN TRANSIENT HEPATIC PORPHYRIA WITH LIVER CIRRHOSIS. (Ger.) Simon, N.; Husz, S.; Masszi, J. (Univ.-Hautklinik, Postfach 480, H-6701 Szeged, Hungary). *Hautarzt* 28(6):303-307; 1977.

A 49-yr-old man with porphyria cutanea tarda and histologically verified liver cirrhosis also had purpuric, urticarial, and telangiectasial skin symptoms as well as a mixed IgM/IgG cryomacroglobulinemia for 8 yr. The liver disease was considered the primary affliction, accompanied by secondary cryomacroglobulinemia. Histology of the upper dermis of purpuric and urticarial skin revealed RBC extravasates, perivesicular infiltrates from polymorphous nuclear neutrophilic leukocytes, lymphocytes, fibroblasts, individual plasma cells, and eosinophil granulocytes. Immunofluorescence of purpuric lesions showed homogenous vessel color, many small granular deposits, thrombus formation with anti-human globulin, IgG, IgM, and complement. In urticarial skin, the granular deposits along the papillary vessels were much more marked than in purpuric lesions. Porphyrin was not detected in either skin lesion. Histology of a liver biopsy showed typical signs of liver cirrhosis. The clinical picture and amount of excreted porphyrin were not influenced by repetitive bleedings, and treatment with prednisolone (30 mg/day for 5 months, decreased to 10 mg/day for 3 further months) was only partially effective. However, porphyrin content in urine returned to normal, which could have been due to long-term steroid treatment or to progression of cirrhosis.

0554 ON EOSINOPHILIC HEPATOPATHY IN EOSINOPHILIC RETICULAR HYPERPLASIA OF THE SKIN. (Ger.) Korting, G. W.; Schramm, P. (Hautklinik, Johannes-Gutenberg-Universitat, Langenbeckstrasse 1, D-6500 Mainz, W. Germany). *Arch. Dermatol. Res.* 259(1):43-47; 1977.

Eosinophilic hepatopathy was diagnosed in a 40-yr-old woman with eosinophilic reticular hyperplasia of the skin. The anamnestic data included endogenous eczema at the age of 15 yr, transient jaundice in 1966, and ampicillin-induced exanthema in 1974. A tumor, tentatively diagnosed as eosinophilic granuloma, was removed from the buccal cavity in 1974, at which time 26% eosinophilia of the blood was found. The patient developed nodules in the mandibular region, nodular infiltration in the submandibular, sternal and thoracic regions, and eczema of the hip and hands. The blood eosinophil count was 33%, the sternal bone marrow showed hypereosinophilia, and Australia antigen was found in the serum. The suspect liver scintigram and the pathological serum enzyme levels (glutamic oxaloacetic transaminase, 76 mU/ml; glutamic-pyruvic transaminase, 187 mU/ml; gamma-glutamyl transaminase, 49 mU/ml) prompted laparoscopy and liver biopsy, which revealed HBsAg-positive chronic persistent hepatitis, proliferation of fibers in the portal region, and focal clusters of eosinophil cells (eosinophilic hepatopathy). The findings indicate that, contrary to current belief, the involvement of internal organs, particularly of the liver, in reticular hyperplasia of the skin seems to be possible.

0555 REYE'S SYNDROME. (Ger.) Wehinger, H. (Universitats-Kinderklinik Freiburg i. Br., W. Germany). *Klin. Paediatr.* 189(3):206-210; 1977.

The clinical symptoms, diagnosis, etiology, pathogenesis, and therapy of Reye's syndrome are presented. The condition is an acute and often fatal childhood syndrome of encephalopathy and fatty degeneration of the liver, marked by rapid development of brain swelling and hepatomegaly and by disturbed consciousness and seizures. The smooth endoplasmic reticulum shows a proliferation and an increase of peroxisomes, and the glycogen content of the endoplasmic reticulum decreases with severity of the disease. The disease is more predominant in girls, and in the majority of cases it is preceded by influenza B or varicella infection. Elevated ammonia and creatinine phosphokinase levels are also common, as is mitochondrial damage. The early disease stages are characterized by lethargy, delirium, and intermittent coma, whereas decerebral symptoms and muscle hypotony precede death. Intensive monitoring of electrolytes, acid-base status, serum osmolarity, and blood sugar is recommended. Therapy with neomycin, citrullin, vitamin K, glucose, and insulin is warranted for all stages. When cerebral edema is present, Mannit and dexamethasone should be given; intubation is required for respiratory alkalosis. Phenobarbital and diphenylhydantoin should be administered when seizures occur.

0556 REYE'S SYNDROME. (Ger.) Bohles, H. (Universitats-Kinderklinik, 8520 Erlangen, Loschgestr. 15, W. Germany). *Dtsch. Med. Wochenschr.* 102(12):446-451; 1977.

Pathogenetic, clinical, biochemical, and therapeutic aspects of Reye's syndrome (RS) are reviewed. Viruses, toxins (aflatoxin), acetylsalicylic acid, isopropyl alcohol, and short-chained fatty acids have been assumed to be the etiological factors by various authors. It was possible to reproduce the symptoms of RS more or less completely in animals by means of aflatoxins, hypoglycine, and 4-pentaenic acid. RS appears to be the final stage of a pathogenetic process that may be of infectious, toxic, or allergic etiology. The hepatic changes in RS include slight enlargement and high consistency of the liver, diffuse fatty degeneration of the parenchymal cells of hexagonal shape, usually without liver cell necrosis, and mitochondrial degeneration. The fat contains no birefringent lipids. Increased hepatic glycogen was often seen, but cholestasis was never found. The laboratory tests show hypoglycemia and usually a low glucose level in the cerebrospinal fluid, increased glutamic-oxaloacetic and glutamic-pyruvic transaminase activities in the liver, and high blood ammonia levels. None of the therapeutic methods tested or proposed have been substantiated. Peritoneal dialysis, blood exchange, and administration of free blood plasma, glucose with insulin, citrulline, and vitamin K have been used with varying success. Quick diagnosis and intensive treatment are essential. Cooperative studies on RS will be necessary to obtain relevant, reliable findings.

557 CURRENT STATUS OF THE PROPHYLAXIS OF WILSON'S DISEASE. (Fre.) Sternlieb, I. (Albert Einstein Coll. Medicine, 1300 Morris Park ve., Bronx, NY 10461). *Rev. Fr. Gastroenterol.* 125):41-44; 1977.

The treatment of 76 Wilson's disease (WD) patients ith 1 g/day D-penicillamine is presented. Sixty atients had classical WD with a reduced ceruloplasmin level (CL) and elevated hepatic copper (HC), had a normal CL and elevated HC, 5 had Kayser-leischer rings, and 8 had a reduced CL. Two atients who did not receive regular therapy eveloped psychic symptoms. Side-effects attributed o D-penicillamine were observed only in three atients: elastosis perforans serpiginosa after 6 yr of therapy, nephrosis (the D-penicillamine was eplaced by triethylenetetramine), and nephrocalcinosis. No intellectual or physical deterioration, owever, occurred in any of the patients during -penicillamine therapy.

558 THE PRESENT STATUS OF LIVER TRANSPLANTATION. (Eng.) Calne, R. Y. (Addenbrooke's Hosp., ills Rd., Cambridge CB2 2QQ, England). *Transplant. roc.* 9(1):209-216; 1977.

ne hundred and fifty-six patients who received liver rafts in Denver (106 patients) and in Cambridge/ing's College Hospital series (50 patients) were tudied. Of these 106 patients, 27 lived 1 yr or ore after liver grafting and 16 were alive at 1-6 r following grafting. Rejection was the main ause of death in about 10% of the cases. Twenty f the 59 patients age ≤18 yr survived more than yr, and 14 are currently living; one of these s the longest survivor (6.3 yr). Of the 50 atients in the Cambridge/King's series, 12 survived more than 6 months, 4 of these lived beyond yr, and 10 are currently living (one for 2.5 yr). he longest survivor (5.2 yr) in this series died f biliary obstruction secondary to calcified sludge ormation blocking the anastomosis between the gallbladder and the recipient common duct. The major omplications resulting in death were biliary tract disasters, particularly fistula formation, anastomotic stenosis, and blockage with sludge or superimposed infections, e.g., pneumonia and intraperitoneal abscess or tumor recurrence. A simple method of short-term liver preservation and a new technique of biliary drainage using the gallbladder as a conduit are suggested to produce gratifying results. The low incidence of progressive uncontrollable liver allograft rejection could contribute to an overall understanding of renal and cardiac grafts.

0559 HETEROTOPIC (AUXILIARY) LIVER TRANSPLANTATION IN MAN. (Eng.) Fortner, J. G.; Kim, D. K.; Shiu, M. H.; Yeh, S. D. J.; Howland, W. S.; Beattie, E. J. (Memorial Hosp., 1275 York Ave., New York, NY 10021). *Transplant. Proc.* 9(1):217-221; 1977.

Experience with and results of heterotopic liver transplants (the recipient's liver remains and the donor liver is transplanted to another area) in 7 patients aged 3-72 yr are presented. Six patients had an entire liver transplanted, and one received only a left lobe graft; the latter patient died about 24 hr postoperatively due to acute congestion of the graft, renal failure, and cardiac arrest. Three patients had well-functioning grafts for prolonged periods of time. One is living and well with a normally functioning graft more than 4 yr after transplantation. One patient lived 8 months with a normally functioning graft and died due to infection in her own liver secondary to obstruction from the bile duct cancer. The third patient initially had an uneventful course when a rejection reaction developed; a minimal increase in immunosuppression led to *Pneumocystis carinii* infection and death at 3.5 months. Serial ^{99}Tc scans in one patient showed homogeneous uptake in both the recipient's graft and patient's liver and spleen without apparent significant quantitative difference from 5th to 54th post-transplant day. Rose bengal uptake and excretion were normal. The causes of transplantation failure in six of the cases were multiple abscesses in recipient liver, breakdown of cholecystojejunostomy, hemorrhage and acute congestion of graft, *Pneumocystis* pneumonia, aspiration pneumonia and monilial esophagitis, and septicemia and progressive necrosis. One patient is alive and well. It is suggested that the heterotopic auxiliary liver transplant is clinically useful for selected patients with end-stage noncancerous liver disease.

0560 SELECTIVE CELIAC ANGIOGRAPHY AND SURGICAL EXPLORATION FOR SUSPECTED LIVER CANCER. A COMPARATIVE STUDY OF 196 PATIENTS. (Eng.) Almersjo, O.; Hafstrom, L.; Rosengren, K.; Wedel, N. (Sahlgren Hosp., Univ. Goteborg, Goteborg, Sweden). *Am. J. Surg.* 131(6):676-679; 1976.

0561 PRIMARY HEPATIC CARCINOMA IN THAILAND. (Eng.) Stitnimankarn, T. (Siriraj Hosp., Mahidol Univ., Bangkok, Thailand). *Gann Monogr. Cancer Res.* 18:123-127; 1976.

0562 LIVER METASTASES: DIAGNOSTIC VALUE OF BLOOD TESTS, SCINTISCANNING AND LAPAROSCOPY. (Ger.) Angehrn, F. G.; Schmid, P.; Pescia, R.; *et al.* (Stadtspit. Triemli, Zurich. Switzerland). *Dtsch. Med. Wochenschr.* 101(28):1047-1055; 1976.

0563 SEMIQUANTITATIVE ASSESSMENT OF HEPATIC FUNCTION IN OUTPATIENTS BY BREATH ANALYSIS AFTER ORAL ADMINISTRATION OF ^{14}C-AMINOPYRINE. (Eng.) Hanik, L.; Eriksson, S. (Dept. Internal Medicine, Univ. Lund, Lund, Sweden). *Scand. J. Gastroenterol.* 12(Suppl. 45):31; 1977.

0564 THE EFFECT OF HEPATIC DEARTERIALIZATION AND REDEARTERIALIZATION ON CARCINOID LIVER METASTASES. (Eng.) Sivula, A.; Sipponen, P. (Univ. Central Hosp., Helsinki, Finland). *Ann. Chir. Gynaecol.* 65(3):168-175; 1976.

0565 SERUM CHOLESTEROL AND BILE ACID IN PRIMARY HEPATOMA. (Eng.) Hirayama, C.; Irisa, T. (Faculty Medicine, Tottori Univ., Yonago, Japan). *Clin. Chim. Acta* 71(1):21-25; 1976.

LIVER AND BILIARY TRACT

Hyperbilirubinemic States

0585 CHOLESTATIC JAUNDICE IN INFANCY: DIAGNOSIS, DIFFERENTIAL DIAGNOSIS AND TREATMENT. (Eng.) Poley, J. R.; Magnani, H. N. (Universitats-Kinderklinik, Prittwitzstrasse 43, 79 Ulm/Donau, W. Germany). *Aust. Paediatr. J.* 12(3): 134-153; 1976.

Common types of persistent cholestatic jaundice (CJ) in infancy are reviewed along with tests for differentiating between intrahepatic cholestasis (IC) and extrahepatic cholestasis (EC). Most infants with CJ may have some type of inflammatory lesion such as seen in neonatal hepatitis (NH) syndromes, or they may have one of the intrahepatic biliary hypoplasia (IBH) syndromes or some type of obstructive lesion of the extrahepatic biliary tree. IBH syndromes probably account for a major group of infants that present with early IC, and patients with IBH present with more severe cholestasis than those with NH. The striking abnormality on biopsy in patients with IBH is the decrease in number and caliber of the bile ducts in portal tracts; sometimes, these bile ducts cannot be identified at all. Three types of lesions characterize EC: true atresia of the common bile duct or hepatic duct, lesions showing obliteration of extensive portions of the sometimes hypoplastic extrahepatic biliary tree, or the absence of recognizable structures reminiscent of bile ducts in the area of the porta hepatis of the hepatoduodenal ligament. The most promising tests for differentiating between IC and EC in infantile CJ are tests for serum 5'-nucleotidase and tests for serum lipoprotein-X (LP-X) combined with cholestyramine (CSM) administration. The absence of serum LP-X in infants with CJ below 7 months of age dictates against a diagnosis of biliary atresia, whereas a positive test (>30 mg/dl) indicates severe cholestasis. When LP-X is measured after CSM administration, a decrease in serum LP-X indicates IC, whereas an increase in serum LP-X indicates EC. Surgical exploration should be reserved for patients in whom an obstructive lesion is unequivocally identified. However, no other test, with the exception of surgery, can determine the type of obstructive lesion present.

0586 STUDY OF THE ETIOLOGY AND PATHOGENESIS OF LOW GRADE NONHEMOLYTIC UNCONJUGATED HYPERBILIRUBINEMIA (GILBERT'S DISEASE). (Eng.) Blueger, A. F.; Krupnikova, E. Z.; Sondore, V. Yu.; Semushina, E. P. (Riga Medical Inst., 12 Padomyu bulv, Riga, USSR). *Acta Hepatogastroenterol. (Stuttg.)* 24(3):140-147; 1977.

Clinical and morphological data on 172 adolescent and adult patients with low-grade nonhemolytic unconjugated hyperbilirubinemia (NUH) were analyzed. The constitutional form (group 1) occurred in 111 patients, the posthepatic form (group 2) in 61. The most common clinical findings were a slight jaundice of the sclerae and abdominal pain plus elevated GOT activity and dysproteinemia. ^{51}Cr RBC survival was shortened in 17/31 patients in group 1 and in 11/15 patients in group 2, the mean values being 16 and 15.5 days, resp., versus a control value of 22.4 days. The mean 24-hr urinary glucuronic acid excretion after menthol ingestion decreased in groups 1 and 2 (1,794 and 1,800 mg, resp.) compared to controls (2,189 mg). Hepatic glucuronyl transferase (GT) activity (77-180 nmol/30 min/mg protein) was low in nine patients and low-normal in one. The mean 24-hr fecal urobilinogen excretion was reduced in groups 1 and 2 (117 ± 35 and 110 ± 45 mg, resp.), but it was increased in 12 patients with hereditary hemolytic jaundice (258 ± 158 mg), compared to control value of 163 ± 15 mg. The hepatocytes showed signs of dystrophy, e.g., vacuolated nuclei, reduced number of microvilli, increased amount of lipofuscin pigment, and large areas of agranular endoplasmic reticulum. Decreased GT activity is an important factor in the pathogenesis of low-grade NUH. The results show not only a disturbance in intrahepatic bilirubin metabolism, but also in other functions of the liver.

0587 PREVENTION OF KERNICTERUS, BASED ON RECENT PROGRESS IN BILIRUBIN CHEMISTRY. (Eng.) Brodersen, R. (Inst. Medical Biochemistry, Univ. Aarhus, DK-8000 Aarhus C, Denmark). *Acta Paediatr. Scand.* 66(5):625-634; 1977.

The binding of bilirubin to albumin, its displacement by fatty acids and drugs, and the importance of plasma pH are reviewed in relation to preventing neurotoxic levels of free bilirubin in kernicterus. Bilirubin IX-α(Z), the only type of bilirubin known to be neurotoxic, is bound reversibly to one high-affinity site on human serum albumin (binding constant at 37 C is 7 x 10^7 M). Fatty acid levels higher than four times the molar concentration of albumin displace bilirubin from its primary binding site, as do certain sulfonamides and a number of other drugs, thereby increasing the risk of kernicterus. Sulfisoxazole is capable of precipitating kernicterus in icteric infants. Plasma pH also affects the binding of bilirubin to albumin. An infant with a plasma pH of 7.05 (severe acidosis) and a safe upper level of 10 nmol/l of free bilirubin has plasma albumin that is less than half-saturated with bilirubin and a plasma bilirubin concentration of about 150-200 μM. After correction of the pH, the equilibrium is shifted in favor of the plasma albumin, which can now carry a bilirubin concentration of 300-400 μM and still have a tolerable level of the free pigment. For all cases of suspected bilirubin displacement, a rational therapy is the i.v. administration of albumin. More binding sites are then provided for bilirubin as well as for the competitor, and, with exchange transfusion, certain amounts of both bilirubin and competitor are removed from the body.

LIVER AND BILIARY TRACT

Nonviral Hepatitis and Hepatic Injury

0591 THE ROLE OF PLASMA MEMBRANES IN HEPATOTOXIC EFFECTS. (Eng.) Frimmer, M. (Institut fur Pharmakologie und Toxikologie, Fachbereich Veterinarmedizin, Universitat Giessen, D-6300 Giessen, W. Germany). *Naunyn Schmiedebergs Arch. Pharmacol.* 297 (Suppl. 1):S15-S19; 1977.

The effect of three different toxins that act directly on hepatic plasma membranes was studied. Phallolysin from *Amanita phalloides* destroyed plasma membranes and killed cells by an outflow of cytoplasm. Leucocidin from *Pseudomonas aeruginosa* produced Ku^+ loss, swelling, and microcirculatory disturbances in perfused livers but the plasma membranes appeared smooth. It is suggested that swelling may be caused by potassium release with simultaneous uptake of sodium and water and that the receptor for the pseudomonas toxin might be an integral protein of the plasma membranes. Phalloidin from *A. phalloides* affects the intravascular pressure and the plasma membrane invagination and vacuolization *in vivo*. However, isolated hepatocytes develop typical protrusions in the presence of phalloidin. To understand the mechanism of action of phalloidin, the protective effects of trypsin-like enzymes (proteases) and phospholipase A were studied in isolated hepatocytes. Chymotrypsin and elastase were less potent than trypsin as protectors. The protective activity of phospholipase A depended on the concentration of the enzyme and the time of preincubation. This protection by phospholipase A was reversible within 1 hr after removal of the enzyme by washing. Both protein and lipid structures appear to be involved in the recognition of phalloidin on the surface of liver cells.

0592 PORTAL HYPERTENSION WITHOUT HEPATIC CIRRHOSIS IN CHRONIC VITAMIN A INTOXICATION. (Ger.)
Kistler, H. J.; Pluer, S.; Dickenmann, W.; Pirozynski, W. (Medizinische Abteilung, Spital Limmattal, CH-8952 Schlieren, Switzerland). *Schweiz. Med. Wochenschr.* 107(24):825-832; 1977.

Chronic vitamin A intoxication developed in a 37-yr-old man with psoriasis vulgaris following intake of vitamin A (700,000 IU/day, p.o.) for 13 months. Initially, the psoriatic lesions cleared, but skin symptoms returned with further intake of vitamin A. The patient developed symptoms typical of chronic vitamin A intoxication; these included deterioration in his general condition, total alopecia, anorexia, weight loss, ascites, edema of the legs, and depression. The patient had abnormal liver function tests and hepatomegaly. Splenoportography revealed portal hypertension. No signs of liver cirrhosis were demonstrated by repeated liver biopsies. The patient improved gradually after discontinuation of vitamin A. Hair growth was evident, and skin lesions were cured with local therapy. Ascites and edema receded following treatment with spirolactone, ethacrynic acid, and furosemide. The patient was also given a tricyclic antidepressant. Serum vitamin A levels decreased after 3 months, and liver function tests gradually returned to normal; signs of portal hypertension completely disappeared. BSP retention returned to normal after 2 yr.

0593 GLUCOSE-DEPENDENT HEPATIC MEMBRANE TRANSPORT IN NONBACTEREMIC AND BACTEREMIC THERMALLY INJURED PATIENTS. (Eng.) McDougal, W. S.; Wilmore, D. W.; Pruitt, B. A., Jr. (Brooke Army Medical Center, Fort Sam Houston, TX 78234). *J. Surg. Res.* 22(6):697-708; 1977.

Hepatic clearance of indocyanine green (ICG) was measured in 106 studies in 25 thermally injured patients, and the effect of bacteremia and various infused substrates on hepatic dye uptake is described. The patients (mean age, 35 yr) had an average total body surface burn of 59%. Seventeen patients subsequently developed positive blood cultures and were restudied. Fourteen serial measurements of dye concentration taken over a 70-min period were computer fitted to describe each disappearance curve, and the two rate constants, k_1, and k_2, were determined (all $r^2>0.94$). ICG plasma disappearance was unimpaired in nonbacteremic patients when glucose or glucose plus amino acids were part of the parenteral regimen ($-k_1=0.241 \pm 0.023$ and 0.255 ± 0.009/min) but were significantly decreased when near isocaloric amounts of glucose-free amino acid solutions were administered ($-k_1=0.150 \pm 0.016$/min, $p<0.001$). Bacteremic patients had markedly impaired ICG hepatic clearance, irrespective of the hypocaloric dietary regimen. Both exclusion of glucose from the nutrient infusates in nonbacteremic patients and bacteremia resulted in a marked reduction in the maximal velocity of the ICG dye transport reaction. Septic patients infused with glucose and insulin improved their clearance of the dye (from $k_1=0.169 \pm 0.029$ to 0.183 ± 0.028/min, $p<0.01$). These alterations could not be related to changes in circulation or perfusion. Urea production varied inversely and endogenous insulin levels directly with the k_1, suggesting that membrane transport is related to the ornithine cycle and/or is influenced by insulin. Optimal metabolic integrity of the hepatocyte is substrate-specific and dependent upon the provision of exogenous energy. Hepatic transport function is limited in bacteremic patients, as well as in burn patients deprived of glucose. Restoration of hepatic transport processes may be achieved by providing sufficient energy in the form of glucose.

Acute Viral Hepatitis

0598 A CRITIQUE OF INTERNATIONAL ASSOCIATION FOR THE STUDY OF THE LIVER (IASL) CRITERIA FOR THE DIAGNOSIS AND TREATMENT OF VIRAL HEPATITIS.

(Eng.) Leevy, C. M. (Coll. Medicine and Dentistry of New Jersey, Newark, NJ 07103). *Rush. Presbyterian-St. Lukes Med. Bull.* 15(2):115-122; 1976.

Criteria established by the International Association for the Study of the Liver (IASL) for the diagnosis of viral hepatitis are critically reviewed. A major diagnostic problem relates to the occurrence of hepatitis due to a virus other than the A or B type. This new form of hepatitis, labeled virus C type, is particularly difficult to differentiate from drug-induced hepatitis. Differentiation of alcoholic hepatitis from viral hepatitis has been facilitated by the detection in serum of an antigen to alcoholic hyalin in early phases of the disease followed by the appearance of antibodies to this glycoprotein, which has been isolated and partially purified. Criteria for chronic and fulminant viral hepatitis do not reflect the prognostic implications of these diseases. There is a need to supplement IASL criteria with information on hepatocyte volume, regenerative capacity, and other factors to properly classify patients with fulminant hepatitis. Diagnostic criteria for chronic persistent and chronic active hepatitis are primarily based on histology; serial biopsies and clinical features compatible with either disease may show lesions of the other disease, owing to sampling or a change in status. Clinical tests for evaluating patients with viral hepatitis have been established on three increasingly sophisticated levels, depending on the medical test facilities available. Level I tests include measuring amino transferase activities, serum protein levels, prothrombin time, dye retention, serum bilirubin level and fractionation, and serum alkaline phosphatase activity, plus liver biopsy, and detection of virus B surface antigen and antibody via immunodiffusion, counter immunoelectrophoresis, and inert particle agglutination. Level II tests include measurements of indocyanine green clearance, serum 5' nucleotidase activity, serum bile acid levels, serum immunoglobulin levels, and alpha fetoprotein level, plus hepatitis B surface antigen and antibody detection by complement fixation, radioimmunoassay, and electron microscopy. Level III tests include measurements of galactose elimination capacity, bile acid clearance, lymphocyte response to hepatitis B surface antigen, hepatitis B core and hepatitis B core antibody detection, and the detection of hepatitis A virus by complement fixation, immune adherence test, and fecal viral particles.

0599 THE SIGNIFICANCE OF THE DIAGNOSIS OF ISOENZYMES IN LIVER DISEASES. 2ND COMMUNICATION: ACUTE HEPATITIS AND ITS COURSE.

(Ger.) Graubaum, H. J.; Wagenknecht, C.; Klimmt, G.; Baumgarten, R.; Schneider, G.; Schimmelpfennig, W.; *et al.* (Institut Physiologische Biologische Chemie der Humboldt-Universitat, DDR-104 Berlin, Hessische Str. 3/4, E. Germany). *Dtsch. Gesundheitsw.* 32(23): 1087-1092; 1977.

Plasma isoenzyme levels, including glutamate dehydrogenase (GOT), aldolase dehydrogenase (ALD), and LDH were determined in 59 patients with acute hepatitis and correlated with the severity, stage, and prognosis of the disease. Marked increases of total ALD, GOT, and LDH were noted shortly after the appearance of the first prodromal symptoms in the first week. In uncomplicated cases of acute hepatitis, M-type LDH levels returned to normal after 2-3 weeks, liver ALD (ALD-L) and GOT-M after 3 weeks and cytoplasmic GOT (GOT-C) after 5 weeks. H-type LDH increased up to the fifth week. High activities of ALD-L, GOT-C, and M-type LDH and a high level of GOT-M were found to indicate severe cellular damage. Normal activities of ALD-L, GOT-M, and M-type LDH with raised GOT-C demonstrate a normalization of hepatitis (late phase), whereas increases in ALD-L, GOT-C, and M-type LDH above normal indicate the early stage. Elevated enzyme levels beyond the eighth week reflect a protracted course, which may be the start of chronic hepatitis. Following a 2-week course of treatment of one patient with prednisolone (1 mg/kg/day), plasma enzyme levels decreased, whereas the specific activity of the isoenzymes in the liver and plasma, excluding H-type LDH, returned to normal. The decrease of the activities in plasma has repeatedly been attributed to a membrane-stabilizing effect of prednisolone, which does not occur in the liver. Bicycle ergometer tests of five patients with prior hepatitis showed low or constant isoenzyme levels after exertion, whereas all eight controls had elevated isoenzyme levels. These results suggest that isoenzymes are eliminated more rapidly in the former group but more tests are needed to corroborate these findings.

0600 STUDIES OF AN OUTBREAK OF ACUTE HEPATITIS A: I. COMPLEMENT LEVEL FLUCTUATION.

(Eng.) Baer, G. M.; Walker, J. A.; Yager, P. A. (P.O. Box 363, Lawrenceville, GA 30246). *J. Med. Virol.* 1(1): 1-7; 1977.

Serum samples from 50 patients who were involved in a hepatitis A outbreak were examined for complement levels and for the presence of antigen-antibody complexes. The outbreak was caused by sewage-contaminated drinking water and involved 49 children and 1 adult. Acute and convalescent serum samples were obtained from the hepatitis patients, and from each of 24 unafflicted matched controls at the same time. Strikingly, the levels of the third and fourth components of complement (C'3 and C'4) were markedly reduced in the acute samples from the sick children but returned to normal in the convalescent ones; the C'3 and C'4 levels in the healthy matched controls were not reduced. In addition, antigen-antibody complexes were found in convalescent sera from some of the sick children. These findings indicate that immune complexes are present in acute hepatitis A and suggest that the techniques for future virus isolation may have to be altered.

0601 HEPATITIS B: NEW ASPECTS, PRACTICAL CONSEQUENCES, VIROLOGY AND EPIDEMIOLOGY.

(Ger.) Deinhardt, F. (Max von Pettenkofer-Institut, Pettenkoferstrasse 9a, D-8000 Munchen 2, W. Germany). *Schweiz. Med. Wochenschr.* 107(15):505-510; 1977.

The epidemiology, virology, serology, and immunization against viral hepatitis are discussed. In addition to the identification and characterization of hepatitis A and B, a third form ("non A-non B" hepatitis) has been recognized. Primary hepatitis is distinct from secondary hepatitis, which frequently is an accompanying symptom of primary infections with Epstein-Barr virus, as seen in infectious mononucleosis. Hepatitis A (short incubation hepatitis) usually occurs as an epidemic and has an incubation time of 20-30 days; it can be prevented or weakened by normal human immune serum globulin (ISG). Hepatitis B (long incubation hepatitis) frequently develops after blood transfusions and is transmitted by blood products and inadequately sterilized instruments or by direct human contact. Perinatal transmission is also possible in children born to mothers who have acute hepatitis B during the last trimester of pregnancy. The incubation time of hepatitis B ranges from 50 to 90 days. Vaccination with a special hepatitis B surface antigen (HBsAg)-ISG (having anti-HBsAg titers of 1:200,000 to 1:500,000 during passive hemagglutination) offers promising protection. Non A-non B hepatitis probably is the most frequent form of post-transfusion hepatitis with an unclear incubation time. There is no cross-immunity between this latter form and he other two. HBsAg is important for the serological diagnosis of hepatitis B; it usually appears in the serum 2-8 weeks prior to the development of clinical symptoms and generally persists for 2-21 weeks. On the other hand, the other components hepatitis B core antigen (HBcAg), e antigen, and virus DNA polymerase can be found temporarily uring the time of active virus multiplication. ersistent e antigenemia is found in the severe and ctive-chronic forms of transient disease and is lways accompanied by Dane particles and DNA poly- erase, which are indicative of an active process n the liver. Recent trials with vaccines from ubunits of HBsAg show promise for controlling epatitis B by active immunization, but caution is arranted due to the many prevailing difficulties.

602 MODIFICATIONS OF CHRONIC HEPATITIS-B VIRUS INFECTION IN CHIMPANZEES BY ADMINISTRATION F AN INTERFERON INDUCER.

(Eng.) Purcell, R. H.; ondon, W. T.; McAuliffe, V. J.; Palmer, A. E.; aplan, P. M.; Gerin, J. L.; *et al.* (Natl. Inst. Allergy and Infectious Diseases, Natl. Inst. Health, Bethesda, MD 20014). *Lancet* 2(7989):757-761; 1976.

Chimpanzees chronically infected with hepatitis B virus were treated with the interferon inducer polyriboinosinic-polyribocytidylic acid-poly-l-lysine carboxymethyl cellulose (PICLC). In two separate experiments, the animals received PICLC (3 mg/kg, i.v.) either once daily for 7 days and every other day for an additional week or once daily for two 6-day periods separated by one non-treatment day, and every other day thereafter for 7 weeks. Serum Dane particle-associated DNA polymerase, e antigen, hepatitis B surface antigen, and intrahepatic hepatitis B surface and core antigens diminished during both treatments. Defective (DNA polymerase-negative) Dane particles increased in titer transiently during treatment; these may play a role in the modulation of hepatitis B virus infection. Humoral immune responses in chronic hepatitis B carrier chimps were unaffected. Interferon inducers (or exogenous interferon) may be useful for the treatment of chronic hepatitis B virus infection.

0603 CLINICAL SIGNIFICANCE OF HEPATITIS B ANTIGEN AND OF HEPATITIS B ANTIBODY.

(Ger.) Renger, F.; Frank, K. H.; Reimann, W.; Tschopel, L.; Muller, Ch. (Medizinische Klinik, Medizinische Akademie "Carl Gustav Carus," Fetscherstrasse 74, DDR-8019 Dresden, E. Germany). *Dtsch. Z. Verdau. Stoffwechselkr.* 36(3/4):121-122; 1976.

The general clinical aspects of hepatitis B antigen (HBAg) and hepatitis B antibody are reviewed. The incidence of carriers of hepatitis B virus is 0.1-20% worldwide. This virus can be transmitted parenterally and orally. HBAg may be present in various body fluids, such as blood, colostrum, sperm, menstrual blood, and feces. The induction of hepatitis is dependent on incubation time, dose inoculated, and the susceptibility of the recipient. The incidence of serum hepatitis can be reduced substantially by weeding out HBAg-positive blood donors and by using blood from one donor instead of pooled blood.

0604 SIMULTANEOUS PRESENCE OF HBsAg AND ANTI-HBs IN THE SERUM OF DIFFERENT SUBTYPES (SEROLOGICAL AND IMMUNOFLUORESCENT STUDIES).

(Eng.) Hess, G.; Arnold, W.; Koesters, W.; Biswas, R.; Hutteroth, T. H.; Meyer zum Buschenfelde, K. H. (Freie Universitat Berlin, Klinikum Charlottenburg, 1000 Berlin 19, W. Germany). *Z. Immunitaetsforsch.* 153(2):143-151; 1977.

Three patients with chronic renal insufficiency who were on hemodialysis and receiving blood transfusions were studied both serologically and by direct and indirect immunofluorescence for the presence of various hepatitis B virus antigens and antibodies. Serum factors were measured by immunodiffusion, counter-immunoelectrophoresis, passive hemagglutination, and/or radioimmunoassay. Liver biopsy revealed two cases of chronic persistent hepatitis and one case of mild chronic active hepatitis. The two women showed the HBsAg subtype *ad* and anti-HBs with the *y* specificity, while the men carried the HBsAg subtype *ay* and anti-HBs with specificity *d*. No antibody with specificity *a* was found in any serum. Using the Raji-cell technique, no circulating complement binding immune complexes were found. Measurements of rheumatoid factor, antimitochondrial antibodies, smooth muscle antibodies, and antinuclear antibodies were negative, except for the latter in one woman (homogeneous type, 1:10 dilution). All sera were positive for e-antigen and negative for anti-e. One woman was followed for 8 months and persistently carried the HBsAg subtype *ad*; after 4 months she also produced anti-HBs with *y* specificity. Liver biopsy slices tested with subtype-specific antisera showed cytoplasmic fluorescence in all cases with anti-HBs subtypes *ad* and *ay*, while nuclear fluorescence was noted with anti-HBc in two cases. In these two cases positive reaction with anti-human IgG was found in the nuclei but not in the cytoplasm. Indirect immunofluorescence with subtype-specific antisera demonstrated a cytoplasmic fluorescence with anti-HBs subtypes *ad* and *ay* in all patients. Liver sections were positive with HBs antibodies to subtype *d* in two patients (who carried subtype *ad* in their sera) and to the subtype *y* in one patient (who carried *ay* in his serum). Autologous serum produced no fluorescence on liver sections, whereas two patients' sera produced a cytoplasmic reaction on liver slices of the third patient and vice versa. It is suggested that the occurrence of HBsAg and anti-HBs with different subtypes in a single patient may be due to two exposures to hepatitis B viruses of different subtypes, one exposure producing an immune tolerance and another an immune response. Chronic renal insufficiency has been demonstrated to produce an impaired immune competence and might be involved in a differential response to HBsAg subtypes.

0605 CORRELATIONS BETWEEN ANTI-ALBUMIN ANTIBODIES AND HBsAG IN HEPATIC PATIENTS.

(Eng.) Lenkei, R.; Babes, V. T.; Dan, M. E.; Mustea, A.; Dobre, I. (Victor Babes Inst., Spl. Independentei 99-1-1, Bucharest 35, 7000 Rumania). *J. Med. Virol.* 1(1):29-34; 1977.

Sera from patients with various hepatic disorders and from healthy controls were examined for the presence of hepatitis B surface antigen (HBsAg) and the incidence and titer of antipolymerized albumin antibodies (AAA). HBsAg detection was done by counterelectrophoresis (CEP) and by reversed passive hemagglutination (RPH). AAA detection was done by immunodiffusion with glutaraldehyde-polymerized human serum albumin (ID-HSA) and by passive hemagglutination (HA-EPA). The incidences of HBsAg in 360 controls, 21 patients with chronic persistent hepatitis, 220 patients with acute viral hepatitis, 64 patients with chronic aggressive hepatitis, and 74 patients with hepatic cirrhosis were 12.8, 52.4, 28.2, 68.8, and 52.7%, resp. The incidences of AAA in these groups were 17.8, 14.3, 69.5, 64.1, and 70.3%, resp., as measured by ID-HSA and 13.9, 33.3, 56.4, 50.0, and 43.2%, resp., as measured by HA-EPA. The AAA concentrations (μg/ml) in these groups were 1,058.3 ± 41.9, 1,075.1 ± 201.2, 479.2 ± 67.6, 504.3 ± 142.4, and 441.3 ± 127.0, resp., as measured by ID-HSA. The AAA titers (log$_2$) for these groups were 4.3 ± 0.2, 6.5 ± 0.8, 7.0 ± 0.4, 6.4 ± 0.5, and 6.4 ± 0.5, resp., as measured by HA-EPA. The incidence of AAA in ID-HSA did not correlate with HBsAg in any of these groups, but the frequency and titer of HA-EPA were higher in patients with HBsAg in each group, though the difference did not reach statistical significance. There was a significant linear correlation between HBsAg, as measured by RPH, and ID-HSA AAA agglutinins ($r=0.15$, $p<0.001$) and HA-EPA AAA precipitins ($r=0.30$, $p<0.001$). By indirect immunofluorescence, eight sera from patients with acute viral hepatitis and three sera from chronic hepatitis patients (negative in CEP and RPH for HBsAg and with high titers in HA-EPA for AAA) were tested for anti-hepatitis B core antibodies (anti-HBc). In eight cases, a bright fluorescence was obtained in the same nuclei as those revealed by standard positive sera. No fluorescence was obtained by the direct application of sheep anti-human immunoglobulin serum labeled with fluorescein isothiocyanate or by other sera from normal subjects previously tested for HBsAg by RPH and for anti-HBc by indirect immunofluorescence. The results indicate that indirect immunofluorescence for the detection of anti-HBc is more sensitive than RPH in the diagnosis of a recent or ongoing hepatitis B virus infection.

0606 HBsAg and HBcAg IN THE LIVERS OF ASYMPTOMATIC HEPATITIS B ANTIGEN CARRIERS. (Eng.)

Tapp, E.; Jones, D. M. (Preston Royal Infirmary, Preston, England). *J. Clin. Pathol.* 30(7):671-677; 1977.

Liver sections from 33 asymptomatic blood donors (22 of whom had multiple biopsies) with constant hepatitis B surface antigen (HBsAg) antigenemia were studied by immunoperoxidase and orcein staining and by electron microscopy. With immunoperoxidase, HBsAg was noted in the liver cell cytoplasm of 34/48 biopsies; 12/33 carriers were negative. Staining varied from a small part of the cell to the entire cell with an intensity from pale yellow to dark brown. A foamy cytoplasm indicated unstained lipid droplets. There was no indication HBsAg was confined to cellular margins. Sheets of cells with diffuse staining affecting up to two-thirds of the lobule were seen while another group of cells could be discerned in which considerably fewer cells were stained. The diffuse pattern was frequent in livers with focal parenchymal necrosis and was seen in two-thirds of biopsies showing cirrhosis. Focal staining was commonly found in cases of chronic aggressive hepatitis. Chronic persistent hepatitis showed both patterns of staining with equal frequency. Subsequent biopsies indicated no change in pattern, with about half the carriers in each group showing some histological deterioration; however, only 1/10 follow-up biopsies showed deterioration in carriers negative for HBsAg. Only 8 (from 4 donors) of 48 biopsies were positive for hepatitis B core antigen (HBcAg) in hepatocyte nuclei, with immunoperoxidase staining varying from a brown to black color. Orcein, reactive for HBsAg, stained only about half the biopsies positive with immunoperoxidase. With electron microscopy, filaments and tubules were observed within dilated endoplasmic reticulum. In 6 (from 3 donors) of 37 biopsies, 20-nm particles were found in the cell nuclei, and those biopsies were all positive with the HBcAg immunoperoxidase procedure. The results indicate that the immunoperoxidase technique is more sensitive than the orcein procedure, that there is an inverse relationship between the content of HBsAg in the cytoplasm and the degree of liver cell destruction, and that HBcAg occurs only in the liver cell nuclei of individuals with chronic hepatitis of the aggressive or persistent type.

0607 e-SYSTEM AND INTRAHEPATOCELLULAR HBcAG AND HBsAG IN HBsAG POSITIVE PATIENTS WITH LIVER DISEASES AND HEALTHY CARRIERS. (Eng.) Hess, G.; Nielsen, J. O.; Arnold, W.; Meyer zum Buschenfelde, K. H. (Second Dept. Internal Medicine, Univ. Mainz, Mainz, W. Germany). *Scand. J. Gastroenterol.* 12(3): 325-330; 1977.

To investigate the prognostic value of the e antigen and the importance of the e antigen as a sign of infectivity, patients with hepatitis B surface antigen (HBsAg)-positive liver diseases and healthy carriers were studied for the presence of e antigen and antibody (anti-e) as well as for intrahepatocellular HBsAg and hepatitis B core antigen (HBcAg). The e antigen was demonstrated in 9 of 12 patients with chronic persistent hepatitis, in 15 of 39 patients with chronic active hepatitis, in 3 of 40 patients with acute type B hepatitis, and in 2 of 9 patients with a protracted course of type B hepatitis. No e antigen was found in healthy HBsAg carriers in patients with complete recovery from type B hepatitis 1 yr after the onset of the disease. Anti-e was detected in 24 of 61 healthy HBsAg carriers with a normal liver histology and in one patient with a mild form of a chronic persistent hepatitis. The presence of e antigen in serum was associated with the presence of HBcAg in the nuclei of the liver cells. Twenty-seven of 29 e-positive patients had HBcAg in the liver cell nuclei. In contrast, none of 20 patients with anti-e in the serum had HBcAg in the liver cells. The results support the hypothesis that the sera of healthy HBsAg carriers are not infectious.

0608 DISCORDANT e ANTIGEN, DNA POLYMERASE ACTIVITY, AND DANE PARTICLE RESPONSES IN TWO PATIENTS REPRESENTING AN INDEX CASE-CONTACT CASE PAIR WITH HEPATITIS B VIRUS INFECTION. (Eng.) Perrillo, R. P.; Gelb, L. D.; Milligan, W. H., III; Wellinghoff, W.; Aach, R. D. (Washington Univ. Sch. Medicine, St. Louis, MO 63110). *J. Infect. Dis.* 136(1):117-121; 1977.

Sera from an index case-contact case pair with hepatitis B virus infection were examined for the presence of e antigen and antibody to e antigen (anti-e), as well as for DNA polymerase activity and the frequency of Dane particles. The index case was a 30-yr-old physician who had no known history of exposure, but who developed acute viral hepatitis. Six months later, chronic aggressive hepatitis was noted. Two months after the onset of illness in the first patient, his wife, who had no known contact other than her husband, developed anicteric, acute viral hepatitis. Six months later, biopsy revealed chronic aggressive hepatitis. Sera from the index patient were consistently e-antigen negative during the 12-month study period, while sera from the contact patient were e-antigen positive during the same period. The contact patient's sera demonstrated an e antigen/anti-e precipitin line at a serum concentration of 1:16 while sera from the index patient failed to manifest this line, even at a threefold concentration of serum. Sera from both patients were positive for hepatitis B surface antigen (HBsAg) during the entire test period, and neither patient had detectable anti-e or antibody to HBsAg. Sera from three healthy persons and from two HBsAg-negative patients were used as controls for the detection of Dane particles and DNA polymerase activity. None of the controls demonstrated any Dane particles, while the index case had between one and five particles per field, and his wife had over 16 particles per field. The DNA polymerase activity of the index patient did not differ from that of controls, while that of the contact patient was unusually high (2,570 counts/min). Sera of both patients appeared to be of the HBsAg subtype *adw*. These responses demonstrate that there is a lack of correlation between the presence of e antigen and the viral strain, and they strengthen the relationship of the e antigen to persistent viremia. The role of the host, rather than that of the infective agent, in the expression of the hepatitis B antigen is emphasized.

0609 HOST RESPONSES TO HEPATITIS B INFECTION IN PATIENTS IN A CHRONIC HEMODIALYSIS UNIT. (Eng.) London, W. T.; Drew, J. S.; Lustbader, E. D.; Werner, B. G.; Blumberg, B. S. (Inst. Cancer Res., 7701 Burholme Ave., Philadelphia, PA 19111). *Kidney Int.* 12(1):51-58; 1977.

To study the nature and variation of hepatitis B infection in patients undergoing chronic hemodialysis, host responses to hepatitis B infection were studied in 222 patients in a chronic hemodialysis unit. From 1970 to 1976, patients were monitored monthly for development of hepatitis B surface antigen (HBsAg), antibody to HBsAg (anti-HBs), and SGPT elevations. Five categories of patients were identified: (1) chronic carriers of HBsAg, (2) transiently HBsAg(+), who developed anti-HBs, (3) HBsAg(-) on admission, who developed anti-HBs without becoming HBsAg(+), (4) anti-HBs(+) on admission, and (5) uninfected, who remained HBsAg(-) and anti-HBs(-). For patients who became HBsAg(+), the probability of becoming a chronic carrier was

62.8% and rose to 88.5% if they had been HBsAg(+) for 5 consecutive months. Men were more likely to become chronic carriers, and women were more likely to develop anti-HBs. Neither age, race, nor type of underlying kidney disease was associated with particular host responses to hepatitis B virus. No effect of hepatitis B infection on mortality was detected. Variation in host response to hepatitis B infection among renal dialysis patients may affect the usefulness of hepatitis B hyperimmune globulin and hepatitis B vaccine and may be related to the outcome of kidney transplantation.

0610 THE EFFECT OF INTRADERMAL ADMINISTRATION OF Corneybacterium parvum ON THE IMMUNE RESPONSE TO HEPATITIS Bs ANTIGEN. (Eng.) Papaevangelou, G.; Sparros, L.; Vissoulis, C.; Kyriakidou, A.; Giokas, G.; Hadzimanolis, J.; *et al.* (Univ. Athens, Medical Sch., Athens 609, Greece). *J. Med. Virol.* 1(1):15-19; 1977.

Because the persistence of hepatitis B surface antigen (HBsAg) in asymptomatic chronic carriers for years or for life has been attributed to a specific defect in the immune response to HBsAg, the immunopotentiating effect of the intradermal administratio of a course of four doses (0.25 ml) of a standard suspension of killed *Corynebacterium parvum* (2 mg/ml) was studied in 10 asymptomatic chronic HBsAg carriers, in 11 persons with antibodies to HBsAg (anti-HBs), and in 6 persons without HBsAg or anti-HBs. HBsAg, anti-HBs, and leukocyte migration inhibition (LMI) studies were performed in pre- and postinoculation blood samples. *C. parvum* produced a substantial increase of anti-HBs titer in subjects with preexisting anti-HBs. However, anti-HBs responses were not induced in carriers. HBsAg was not eliminated, and its titer remained practically unchanged in carriers. These results support the hypothesis that in carriers the specific defect in the immune response to HBsAg possibly exists at the B cell level.

0611 NECROSIS OF THE HEPATOCYTES WITH HEPATITI B SURFACE ANTIGEN: OCCURRENCE IN A CHRON HEPATITIS B SURFACE ANTIGEN CARRIER. (Eng.) Karasawa, T.; Shikata, T. (Faculty Medicine, Univ. Toky Tokyo, Japan) *Arch. Pathol. Lab. Med.* 101(6):280-285; 1977.

Light and electron microscopy of a liver specimen from a 25-yr-old man who was an asymptomatic chronic hepatitis B surface antigen (HBsAg) carrier for at least 1 yr and 8 months are reported. No anti-HBsAg was demonstrated in the serum of this patient. The microscopic findings revealed small lymphocytes and macrophages in close contact with liver cells, partial hepatocyte cytolysis of varying degrees, lytic hepatocyte necrosis, and the complete loss of a few hepatocyte with HBsAg in the cytoplasm. HBsAg or HBsAg-associated material in the cytoplasm was found only in either necrotic liver cells or in liver cells with ground glass appearing cytoplasm. Conventional immunofluorescence studies revealed HBsAg not only in the cytoplasm of hepatocytes but also on the cell membrane. Only hepatocytes with HBsAg both in the cytoplasm and on the cell membrane were necrotic. No IgG or IgM was detected on the cell membrane of the liver cells or in the necrotic foci. Complement component 3 was not present in the necrotic foci. The above evidence most likely rules out not only the involvement of cytotoxic antibody- and complex-mediated humoral immune responses but also that of antibody-directed cell-mediated cytotoxicity or of a cytotoxic mechanism whereby nonspecific normal lymphoid cells (supposedly either bone marrow-derived lymphocytes or macrophages) destroy target cells coated with antibody molecules. Thus, the liver cell injury in this case was probably due to specific contact of hepatocytes with killer cells which are immunologically activated thymus-derived lymphocytes (contact killing).

0635 LIVER BIOPSY IN HEMOPHILIA A. (Eng.)

Lesesne, H. R.; Morgan, J. E.; Blatt, P. M.; Webster, W. P.; Roberts, H. R. (Univ. North Carolina Sch. Medicine, Chapel Hill, NC 27514). *Ann. Intern. Med.* 86(6):703-707; 1977.

The results of percutaneous liver biopsy, under the coverage of glycine-precipitated factor VIII, in six patients with hemophilia A who had persistently abnormal liver function tests for at least 6 months, are described. Each patient was checked for the presence of an inhibitor of factor VIII; if no inhibitor was present, the patient received an infusion of glycine-precipitated factor VIII calculated to raise his factor VIII level to 100%. Blood was drawn after the infusion, and a factor VIII assay was done to be certain that the *in vivo* recovery and half-life of factor VIII were normal. If inhibitor was found, the biopsy was not done. Factor VIII, calculated to raise the factor VIII level to 100%, was administered just before the biopsy. The level was kept at about 75% of normal for 72 hr after the biopsy. Three patients had chronic active hepatitis, and three had chronic persistent hepatitis. No complications were encountered as a result of the biopsy procedure. These results suggest that percutaneous liver biopsy should be considered in patients with hemophilia A with continuously abnormal liver function tests to establish a histologic diagnosis and to guide further therapy.

0636 FOLLOW-UP OBSERVATION OF 52 PATIENTS WITH CHRONIC AGGRESSIVE HEPATITIS. (Ger.)

Wyss, G.; Stalder, G. A.; Bianchi, L. (Medizinische Universitats-Poliklinik, Hebelstrasse 1, CH-4056 Basel, Switzerland). *Schweiz. Med. Wochenschr.* 107 (15):520-523; 1977.

The results of the regular clinical, biochemical, and bioptic follow-up of 52 patients (31 men, 21 women, average age 49.5 yr) with histologically proven chronic aggressive hepatitis (CAH) are presented. The length of the follow-up was 0.5-9 yr (average 31 months). The pathological findings included hepatomegaly in 15 cases, spider nevi in 9, palmar erythema in 7, Dupuytren's contracture in 3, and ascites in 3. Pathological serum bilirubin levels were found in 19%, pathological serum glutamic-oxaloacetic transaminase levels in 89%, pathological serum glutamic-pyruvic transaminase levels in 91%, and pathological alkaline phosphatase levels in 13.5%. Fourteen men and 9 women were HBsAg-positive; 4 men and 3 women (among 42 patients) were HBs-antibody-positive; antinuclear antibodies were found in 16 men and 13 women, and anti-smooth muscle antibodies in 17 men and 13 women. The first biopsy revealed CAH in 64% of all cases. Twenty-two patients already had liver cirrhosis at the time of the histological diagnosis of CAH. Six patients were treated with the combination of imurel and prednisone on the basis of adequate indications (histological diagnosis, chronic process, tenfold increase of the transaminase level or fivefold increase of the transaminase level with twofold increase of the gammaglobulin level). Five patients responded to the therapy. Six patients died during the follow-up; the cause of death was hemorrhage of esophageal varices in one case, hepatoma in two cases, bronchial carcinoma in two cases, and carcinoma of the pancreas in one case. The clinical and laboratory findings remained fairly constant during the follow-up period in patients with mild CAH. Exacerbation was seen only in those patients in whom the first biopsy revealed decompensated liver cirrhosis and ascites.

0637 SEROLOGICAL EVIDENCE OF HEPATITIS B INFECTION IN PATIENTS WITH CHRONIC LIVER DISEASES: RADIOIMMUNOASSAY OF HBsAg AND ANTI-HBs. (Eng.)

Skinhoj, P.; Nielsen, J. O.; Dietrichson, O. (Dept. Infectious Diseases, Rigshospitalet, Copenhagen, Denmark). *Scand. J. Gastroenterol.* 12(5):615-619; 1977.

The prevalence of hepatitis B surface antigen (HBsAg) and anti-HBs was determined by a sensitive double-antibody radioimmunoassay technique in 394 patients with chronic liver diseases. The patients were divided into five groups on the basis of information about their alcohol consumption and liver diseases, i.e., patients with 1) cirrhosis of the liver (199), 2) primary biliary cirrhosis (18), 3) steatosis (79), 4) chronic active hepatitis without cirrhosis (74), and 5) chronic persistent hepatitis (24). HBsAg was demonstrated in 37 of 98 consecutive patients with chronic hepatitis and in 14 of 108 patients with nonalcoholic cirrhosis. HBsAg was not found in any of the patients with steatosis, alcoholic cirrhosis, or primary biliary cirrhosis. In the patients with chronic hepatitis, HBsAg or anti-HBs was demonstrated in 83% of the patients below 40 yr of age in contrast to 48% of the patients over 40 yr of age. It is concluded that, in Denmark, the majority of patients with chronic aggressive or persistent hepatitis have serological evidence of previous contact with hepatitis B virus (HBV) infection. This is in contrast to patients with other chronic liver diseases, in whom only a minor proportion of the nonalcoholic cases appear to have been exposed to HBV infection.

0638 DNA BINDING ANTIBODIES IN HBsAg POSITIVE AND NEGATIVE ACUTE AND CHRONIC LIVER DISEASE [Abstract]. (Eng.)

LIVER AND BILIARY TRACT

Alcoholic Liver Disease

0646 PHARMOKINETICS AND PHARMACODYNAMICS OF ETHANOL, WHISKEY, AND ETHANOL WITH n-PROPYL, n-BUTYL, AND ISO-AMYL ALCOHOLS. (Eng.) Auty, R. M.; Branch, R. A. (Fisons Ltd., Pharmaceutical Div., Res. and Development Lab., Bakewell Rd., Loughborough Leics, England). *Clin. Pharmacol. Ther.* 22(2):242-249; 1977.

To determine whether higher aliphatic alcohols exert any effect on the pharmacology of ethanol, plasma ethanol concentration, reaction time, and EEG were recorded in six normal men after ingestion of ethanol alone (group 1), whiskey (group 2), or a mixture of ethanol, n-proponol, n-butanol, and iso-amyl alcohol (group 3). The peak plasma ethanol concentration and the total area under the plasma concentration:time curve of ethanol did not depend upon the type of drink given, but the half-life of the terminal exponential phase of ethanol elimination was longer in group 3. In each study period, reaction time increased, there was a relative increase in delta activity (2-3 Hz), and a fall in mean dominant frequency in EEG activity. The extent of increase in reaction time depended on the rate of increase in plasma concentration and correlated with the concentration of ethanol while the plasma concentration of ethanol was falling. Differences in the effects of ethanol between study periods were minimal.

0647 ULTRASTRUCTURE OF PERIPORTAL AND CENTRILOBULAR HEPATOCYTES IN HUMAN FATTY LIVER OF VARIOUS AETIOLOGY. (Eng.) Petersen, P. (Rigshospitalet, 2100 Copenhagen, Denmark). *Acta Pathol. Microbiol. Scand.* [*A*] 85(3):421-427; 1977.

The ultrastructure of periportal and centrilobular hepatocytes of two alcoholic patients with fatty liver, two diabetic patients, and two obese patients were compared with that of hepatocytes in two patients with normal livers. A striking difference between periportal and centrilobular hepatocytes in all cases of fatty liver was demonstrated. The periportal hepatocytes contained abnormal mitochondria, while centrilobular hepatocytes had normal mitochondria, but fatty vacuoles, peroxisomes, and lysosomes were more abundant. The nature and degree of ultrastructural changes showed no correlation with etiology of the fatty liver. The normal livers showed no such changes or distinct differences between periportal and centrilobular hepatocytes.

0648 THE HEPATIC CONVERSION OF VITAMIN D IN ALCOHOLICS WITH VARYING DEGREES OF LIVER AFFECTION. (Eng.) Lund, B.; Sorensen, O. H.; Hilden, M.; Lund, B. (Frederiksberg Hosp., Copenhagen, Denmark). *Acta Med. Scand.* 202(3):221-224; 1977.

The seasonal variations in circulating 25-hydroxycholecalciferol (25-HCC) were studied in 102 alcoholics with fatty liver disease without histologic signs of cirrhosis, in 35 patients with alcoholic cirrhosis, and 596 normal controls. Alcoholics had generally lower 25-HCC values than did the controls, particularly in the summer. This was explained primarily by insufficient diet and reduced exposure to sunshine. The ability of the liver to hydroxylate in the 25-position was studied in three groups of alcoholics with fatty liver disease without cirrhosis, compensated cirrhosis, or severely incompensated cirrhosis. All three groups exhibited a significant increase in serum 25-HCC following the p.o. administration of cholecalciferol (1,200 U daily for 7 days). Similar rises were seen 7 days after a single injection of 10,000 U cholecalciferol. These findings indicate a normal intestinal absorption of vitamin D, even in advanced alcoholic liver disease, and are inconsistent with a severely damaged 25-hydroxylation capacity in these patients. Osteomalacia due to impaired liver hydroxylation of vitamin D cannot therefore explain the increased fracture rate and the decreased bone mass that have been described in alcoholics.

Cirrhosis

0659 "TO SELECT BETTER--TO SHUNT BETTER." PREREQUISITES FOR A BETTER PORTACAVAL SHUNTING IN LIVER CIRRHOSIS.

(Ger.) Thiel, H.; Wolter, J. (Med. Univ.-Klinik, Josef-Schneider-Strasse 2, 8700 Wurzburg, W. Germany). *Fortschr. Med.* 95(17):1159-1166; 1977.

Criteria that may improve the results of portacaval shunting in liver cirrhosis are discussed. Postoperative liver failure and portasystemic encephalopathy have frequently been reported after portacaval shunting; these may be due to a further reduction in hepatic blood flow, deprivation of the liver of portal venous blood supply with essential substances, and insufficient criteria for the selection of patients for this procedure. Better selection of patients is recommended, involving a complete evaluation of functional liver volume, the reaction of the hepatic artery to a portavenous increased or decreased blood flow, and new techniques to measure preoperative hemodynamics in liver cirrhosis (such as the transumbilical portal vein catheterization by means of a balloon catheter and transluminal portal vein injection with labeled microspheres for the determination of intrahepatic shunt volume). Differentiated shunt techniques (according to individual hemodynamic and functional data) may improve treatment results, especially for selective decompression and liver arterialization.

0660 LEFT SIDED SEGMENTAL PORTAL HYPERTENSION FOLLOWING MESOCAVAL INTERPOSITION SHUNT.

(Eng.) Witte, C. L.; Ovitt, T. W.; Witte, M. H.; Clark, D. S. (Univ. Arizona Coll. Medicine, Tucson, AZ). *Surg. Gynecol. Obstet.* 145(2):169-174; 1977.

Experience with three cirrhotic patients in whom a mesocaval interposition shunt was carried out is presented. Following the procedure, bleeding esophageal varices recurred in two patients, and left sided portal hypertension partially persisted in one patient. Angiographic and pressure studies of the portal system demonstrated effective decompression of the greater splanchnic venous system but continued lesser splanchnic venous hypertension. Recurrent variceal hemorrhage ceased following emergency splenectomy. In contrast to what occurs following a standard portacaval shunt, after an interposition mesocaval shunt, altered jet streaming of mesenteric blood flow may divert gastrosplenic venous drainage away from the interposition shunt with persistence of lesser splanchnic venous hypertension. Recognition of this entity and of the need for splenectomy is advocated.

0661 CHRONIC HEPATIC ENCEPHALOPATHY. A PSYCHOMETRICAL STUDY.

(Eng.) Rehnstrom, S.; Simert, G.; Hansson, J. A.; Johnson, G.; Vang, J. (Dept. Surgery, Univ. Lund, Lund, Sweden). *Scand. J. Gastroenterol.* 12(3):305-311; 1977.

The type and degree of intellectual impairment in hepatic encephalopathy was studied in 41 patients, and the influence of the liver disease etiology and of portasystemic shunts on this impairment was investigated. Psychometric tests were carried out in 41 patients with liver cirrhosis and suspected hepatic encephalopathy and compared with EEG examinations and clinical investigations. Marked intellectual impairment was noted frequently even when the clinical investigation was normal. This difference was mainly due to the preserved verbal ability of the patient. The etiology of the cirrhosis did not influence the test results. Male cirrhotic patients, with and without alcoholism, showed significantly more intellectual impairment than alcoholics without cirrhosis. Patients with portasystemic shunts showed only slightly reduced intellectual ability compared with those without shunts.

0662 RECTAL ^{13}N-AMMONIA TEST (^{13}N-LIVER/HEART RATIO), HEPATIC SINUSOIDAL PRESSURE AND PREVAILING PORTAL FLOW DIRECTION IN CIRRHOSIS OF THE LIVER.

(Eng.) Hazenberg, H. J. A.; Gips, C. H.; Beekhuis, H.; Kruizinga, K. (Dept. Medicine, St. Jozefziekenhuis, Deventer 6600, Netherlands). *Acta Hepatogastroenterol. (Stuttg.)* 23(5):319-327; 1976.

Twelve of 26 patients with liver cirrhosis who had abnormally low 20-min liver/heart ^{13}N activity ratios (<2.25) were compared with cirrhotics who had normal ^{13}N liver/heart activity ratios after rectal administration of ^{13}N-ammonia in terms of several parameters relevant to liver cirrhosis. An abnormal conventional rectal arterial ammonia test (a rise of 17 μM ammonium ion, portasystemic shunts), an abnormally low urea index (1.2, prevailing hepatofugal portal venous flow direction), marked portal hypertension (hepatic sinusoidal pressure of >8 mm mercury), ascites, and extreme enlargement of the spleen occurred significantly ($p=0.04$) more often in patients with abnormally low ^{13}N liver/heart ratios than in those with ratios of 2.25 or greater. There was no correlation between the ^{13}N liver/heart ratio and the absence or presence of esophageal varices. The noninvasive rectal ^{13}N-ammonia test appears to be a convenient and informative test for the diagnosis of liver cirrhosis.

0663 RECTAL ADMINISTRATION OF ^{13}N-AMMONIA IN CIRRHOSIS OF THE LIVER.

(Eng.) Hazenberg, H. J. A.; Gips, C. H.; Beekhuis, H.; Vaalburg, W. (Dept. Medicine, St. Jozefziekenhuis, Deventer 6600, Netherlands). *Acta Hepatogastroenterol. (Stuttg.)* 23(5):308-318; 1976.

^{13}N-activity was measured during 20-min periods in the liver, spleen, heart, lungs, and forearm of 16 controls and 26 cirrhotic patients after the rectal administration of ^{13}N-labeled ammonium acetate solution. In all subjects, ^{13}N activity appeared in the liver 1 min after rectal administration, although, in some patients with cirrhosis, visualization of the liver was faint. At all times during the 20-min measurement period, liver activity was lower in cirrhotics than in controls ($p<0.01$). Liver/heart activity ratios were more discriminating between controls and cirrhotics ($p<0.05$ at all measurement times) than liver/lung and liver/spleen ratios. In controls, the 20-min liver/heart ratio was the most suitable ratio for determining the normal range (2.25-4.15). An abnormally low (<2.25) liver/heart ratio of ^{13}N activity at 20 min after rectal administration was observed in 12 of the 26 patients with cirrhosis. The advantages of the rectal ^{13}N-ammonia test are its noninvasiveness, giving no discomfort to the patient, the rapid disappearance of radioactivity, and the rapidity with which results are obtained.

0664 HEPATIC SUBCELLULAR DISTRIBUTION OF COPPER IN PRIMARY BILIARY CIRRHOSIS: COMPARISON WITH OTHER HYPERHEPATOCUPRIC STATES AND REVIEW OF THE LITERATURE. (Eng.) Owne, C. A., Jr.; Dickson, E. R.; Goldstein, N. P.; Baggenstoss, A. H.; McCall, J. T. (Mayo Clinic, Rochester, MN). *Mayo Clin. Proc.* 52(2):73-80; 1977.

The subcellular distribution of copper was studied in the liver of 17 normal adults, 1 newborn infant, and 35 patients with liver disease, including 4 with primary biliary cirrhosis. The findings were compared with those for the distribution of copper in the liver cell in normal, copper-laden, and copper-deficient adult rats, in newborn rats and pigs, and in adult pigs. A number of these livers were homogenized and divided into five particulate fractions, as well as the supernatant fraction, for copper analyses. Except in one category, it was found that the greater the total liver copper concentration, the greater the proportion in the larger subcellular particles and nuclei. The exception was patients with primary biliary cirrhosis and with very high total hepatic copper, with 45-75% of that copper residing in the supernatant fraction. In the seriously copper-deficient rat, the total hepatic copper was about half the normal amount. In this case, the shortage was reflected almost entirely in the supernatant fraction. By contrast, five patients with liver disease, who had hepatic copper concentrations below the normal range, had most of the copper in the supernatant fraction. It was also found that the copper content of blood exuding from the cut surfaces of the liver was about the same as the copper content of the liver itself.

0665 ESTRONE AND ESTRADIOL IN PATIENTS WITH CIRRHOSIS OF THE LIVER: EFFECTS OF ACTH AND DEXAMETHASONE. (Eng.) Kley, H. K.; Keck, E.; Kruskemper, H. L. (Medizinische Universitatsklinik, Moorenstrasse 5, 4000 Dusseldorf, W. Germany). *J. Clin. Endocrinol. Metab.* 43(3):557-560; 1976.

The influence of the adrenal gland on plasma estrogen levels was investigated in 12 men with hepatic cirrhosis and in 12 healthy male controls. Cirrhotic patients showed normal base cortisol levels (122 ± 41 ng/ml) compared with controls (122 ± 41 ng/ml). Under basal conditions, cirrhotic patients showed moderately higher ($p<0.05$) plasma estradiol levels (36.0 ± 4.7 pg/ml) and considerably higher ($p<0.01$) plasma estrone levels (67.8 ± 20.8 pg/ml) compared with controls (28.5 ± 5.4 and 32.5 ± 5.6 pg/ml for estradiol and estrone, resp.). The administration of ACTH (1 mg, i.v.) significantly ($p<0.01$) increased cortisol and estrone levels to values of 434 ± 68 ng/ml and 139.6 ± 27.5 pg/ml, resp., in cirrhotics and values of 412 ± 63 ng/ml and 59.8 ± 8.5 pg/ml, resp., in controls. Estradiol levels did not significantly change during ACTH stimulation in either group. Adrenal gland suppression with dexamethasone (1.5 mg, p.o., 3 times/day) for 5 days significantly reduced estrone and estradiol levels from basal values of 72.6 ± 26.8 pg/ml and 35.5 ± 2.1 pg/ml, resp., to values of 37.1 ± 17.6 ($p<0.05$) and 23.9 ± 3.6 ($p<0.001$), resp., in cirrhotics and from basal values of 33.3 ± 6.5 pg/ml and 25.5 ± 4.8 pg/ml, resp., to values of 12.0 ± 4.0 ($p<0.001$) and 15.9 ± 4.7 ($p<0.01$), resp., in controls. The absolute decrease of estrone was significantly greater ($p<0.005$) in cirrhotics than in controls, although suppressed plasma levels of estrone, as well as of estradiol, were still higher ($p<0.05$) than those of controls. These findings indicate that the elevated plasma estrone levels in cirrhotic patients are predominantly due to adrenal production and that peripheral conversion of androgens to estrone rather than to estradiol is more effective in sustaining plasma estrogen levels in this disorder.

0666 ENDOTOXAEMIA AND RENAL FAILURE IN CIRRHOSIS AND OBSTRUCTIVE JAUNDICE. (Eng.) Wilkinson, S. P.; Moodie, H.; Stamatakis, J. D.; Kakkar, V. V.; Williams, R. (King's Coll. Hosp. and Medical Sch., London SE5 8RX, England). *Br. Med. J.* 2(6049):1415-1418; 1976.

The possible role of endotoxins in the pathogenesis of renal failure was investigated in 45 patients with cirrhosis and 12 with obstructive jaundice. Twenty-five of the 45 cirrhotic patients had renal failure, and 21/25 had endotoxemia. None of these 21 patients had other evidence of gram-negative infection at the time of the study, and the endotoxemia was therefore probably due to impaired hepatic clearance of toxins normally absorbed from the gastrointestinal tract. In contrast, bacteriological evidence of gram-negative infection was found in four of six patients with obstructive jaundice and endotoxemia. Only 2/20 cirrhotics without renal failure had endotoxemia, and there was a highly significant difference ($p<0.001$) between this group and the renal failure patients. None of the six patients with obstructive jaundice and normal renal function had endotoxemia. The results indicate that there is a close relation between endotoxemia and renal failure in liver diseases.

0667 IMMUNE RESPONSE TO ϕX 174 IN MAN. 5. PRIMARY AND SECONDARY ANTIBODY PRODUCTION IN PRIMARY BILIARY CIRRHOSIS. (Eng.) Thomas, H. C.; Holden, R.; Jones, J. V.; Peacock, D. B. (Royal Free Hosp., Hampstead, London N.W. 3, England). *Gut* 17(11):844-848; 1976.

The primary and secondary immune response to an i.v. antigenic challenge with the bacteriophage ϕX 174 was studied in 12 patients with primary biliary cirrhosis. Patients were injected with 2.0×10^9 plaque-forming units (PFU) of ϕX 174, and blood samples were collected for 28 days. A second injection was given between the 28th and 42nd days, and blood samples were collected for one month. All patients had a normal immunological response to the first injection. After the second injection, four patients had a normal response, and eight demonstrated a marked reduction in IgG and in the concentration of peripheral T cells. The ratio of serum IgM to IgG was significantly ($p<0.25$) increased in the eight patients with impaired immunological response after the second injection. There was no correlation between the degree of alteration of the secondary immune response to ϕX 174 and the severity of the liver cirrhosis, as shown by degree of cholestasis or hepatocellular necrosis.

LIVER AND BILIARY TRACT

Gallbladder and Biliary Tract Diseases

0688 CRITICAL EVALUATION OF PERCUTANEOUS TRANSHEPATIC CHOLANGIOGRAPHY. (Ger.) Gattinger, A.; Schmoller, H.; Suwandschieff, N. (Rontgendiagnostisches Zentralinstitut des Landeskrankenanstalten, Mullner Hauptstrasse 48, A-5020 Salzburg, Austria). *Wien. Med. Wochenschr.* 127(7): 218-221; 1977.

The results of percutaneous transhepatic cholangiography (PTC) in 33 patients with suspected bile duct obstruction are presented. Puncture of the ducts was impossible in five cases. The cholangiogram was unremarkable in three cases. Bile duct obstruction due to malignant tumor was diagnosed in 15 cases; all these cases were verified at surgery. The tumors included carcinomas of the gallbladder, head of the pancreas, and of the ampulla of Vater. The cholangiogram showed obstruction due to stones in six cases; the diagnosis was correct in five of six cases, while carcinoma of the head of the pancreas was found in the sixth. Cicatricial stenosis was diagnosed in four cases; this diagnosis was correct in two cases, while recurrent tumor and sandpaper gallbladder were found at surgery in the other two cases. The rate of correct cholangiographic diagnosis was 85.7%. The findings indicate the value of percutaneous transhepatic cholangiography in the diagnosis of obstructive jaundice. This test should not be performed on inoperable patients, nor in those with severe disturbance of blood clotting.

0689 ENDOSCOPIC PAPILLOTOMY (EPT). (Eng.) Manegold, B. C. (Klinikum Mannheim der Universitat Heidelberg, Mannheim, W. Germany). *Chir. Gastroenterol.* 10(4):433-435; 1976.

Experience with endoscopic papillotomy for the treatment of papillary stenosis and small common bile duct stones is presented. This procedure was indicated for common bile duct stones in 58 patients, for papillary stenosis in 3, and for a rare case of obstructive jaundice caused by a foreign body having moved from its bed in the liver into the main bile duct in 1. Endoscopic papillotomy was successful in 55 cases, and complete discharge of concrements was proved in 48. In four cases, papillotomy was successful, but concrements were left behind, making choledochotomy necessary. The procedure was complicated by perforation in two cases, by pancreatitis in three, and by cholangitis in one; these patients were treated conservatively, and all survived. Papillotomy was unsuccessful in seven cases. The papilla was not cannulated in four cases; a juxtapapillary diverticulum was present in one case; and technical difficulties occurred in two cases. Endoscopic papillotomy is an effective, low-risk method for the treatment of papillary stenosis and small common bile duct stones in aged patients. Its success depends upon the length of the incision, the diameter of the stone, and the anatomical form of the prepapillary duct.

0690 ANAEROBIC BACTERIA IN BILIARY DISEASE IN ELDERLY PATIENTS. (Eng.) Shimada, K.; Inamatsu, T.; Yamashiro, M. (Tokyo Metropolitan Geriatric Hosp., 35-2, Sakae-cho, Itabashi-ku, Tokyo 173, Japan). *J. Infect. Dis.* 135(5):850-854; 1977.

Gallbladder bile from 52 elderly subjects (mean age 73.4 yr) who had undergone biliary tract surgery was examined for the presence of bacteria. Thirty-three patients had not been given antibiotics before their operations. Twelve patients had sterile bile, 18 specimens of bile yielded anaerobes as well as aerobes, and 22 yielded aerobic bacteria only. *Escherichia coli* was the most commonly isolated organism (30 strains). *Bacteroides fragilis* was the most frequently encountered anaerobic bacterium and was found in 15 patients. The *Klebsiella-Enterobacter* group was the second most commonly isolated group and *B. fragilis* was third. *Clostridium perfringens* was recovered in 10 bile specimens. Anaerobic bacteria were recovered more frequently in patients with ductal obstruction. The relatively frequent isolation of anaerobes, especially of *B. fragilis*, may be related to the anaerobic techniques used, to the age of the patients, and to the high incidence of pigment stones among the subjects (36/39 patients with cholelithiasis).

0691 BILIARY LIPID SECRETION IN CHOLESTEROL GALLSTONE DISEASE: THE EFFECT OF CHOLECYSTECTOMY AND OBESITY. (Eng.) Shaffer, E. A.; Small, D. M. (Montreal General Hosp., 1650 Cedar Ave., Montreal, Quebec, H3G 1A4, Canada). *J. Clin. Invest.* 59(5):828-840; 1977.

To define the biliary secretory mechanism(s) responsible for the production of abnormal bile leading to cholesterol gallstone disease, the rate of biliary lipid secretion was measured by a duodenal marker perfusion technique, and the bile salt pool was estimated simultaneously by isotope dilution. Two groups of control patients expected to have a normal biliary lipid composition (14 without hepatobiliary disease and 6 with pigment gallstones) were compared with two groups expected to have abnormal bile (10 nonobese patients with cholesterol gallstones and 7 obese subjects without gallstones). Both control groups had nearly identical biliary lipid secretion rates and a corresponding low relative molar concentration of cholesterol. Two different secretory mechanisms were responsible for the abnormal bile in the experimental groups. In the nonobese patients with cholesterol gallstones, bile salt and phospholipid secretion rates were reduced significantly. Conversely, the grossly obese subjects had an increased cholesterol secretion. To determine how cholecystectomy improves biliary lipid composition, three groups of gallstone patients (6 with pigment stones, 4 grossly obese with cholesterol stones, and 13 nonobese with cholesterol stones) were examined after full recovery from surgery. In the nonobese patients with cholesterol gallstones, bile salt and phospholipid secretion increased significantly, causing a definite improvement in bile composition. Cholecystectomy produced a similar but less marked trend in the obese patients with cholesterol stones and in the patients with pigment stones. Cholesterol secretion, however, was unaffected by surgery. The bile salt pool was small in the nonobese patients with cholesterol gallstones, and it became slightly smaller after cholecystectomy. The pool was significantly reduced by cholecystectomy in the pigment stone patients and in the obese patients with cholesterol gallstones. Cholecystectomy in all three groups caused a greater fraction of the pool to cycle around the enterohepatic circulation each hour. This more rapid cycling increased bile salt and phospholipid secretion, and was responsible for the improved composition found after cholecystectomy.

0692 FROM MICROLITH TO GALLSTONE. (Eng.) Van de Wal, J. W. M. (St. Elisabeth Ziekenhuis, Amersfoort, Netherlands). *Tijdschr. Gastroenterol.* 20(2):101-112; 1977.

The relationship between gallstone type and gallbladder histopathology was examined in an unselected series of 120 cholecystectomized patients. Among 14 patients with normal gallbladder histology, cholesterol microliths were found in 8, cholesterol mulberry calculi in 3, and other types of calculi in 3. In 11 patients with hypertrophy and hyperplasia of the gallbladder musculature, cholesterol microliths were found in 2, cholesterol mulberry calculi in 2, and other types of calculi in 7. Cholesterol microliths were found in 1 patient, cholesterol mulberry calculi in 4, and other types of calculi in 6 among 11 patients with minimal signs of gallbladder inflammation. In this latter group, there was an increase in the faceting and deposits of gallstones. Among 84 patients with signs of acute-chronic gallbladder inflammation, cholesterol microliths were found in 5, cholesterol mulberry calculi in 4, and calculi of all sizes, shapes, colors, and compositions in 75. As the condition of the gallbladder progresses from normal to pathological, the proportion of cholesterol microliths decreases in relation to other types of calculi. Muscular hypertrophy and hyperplasia may constitute the first visible alteration of the gallbladder wall during gallstone formation.

0693 OCCURRENCE OF DISSEMINATED INTRAVASCULAR COAGULATION (DIC) IN OBSTRUCTIVE JAUNDICE AND ITS RELATION TO BILIARY TRACT INFECTION. (Eng.) Takeda, S.; Takaki, A.; Ohsato, K. (Kyushu Univ. Faculty Medicine, Fukuoka, Japan). *Jpn. J. Surg.* 7(2):82-89; 1977.

Coagulation studies were done on 78 consecutive cases of obstructive jaundice with or without biliary tract infection to emphasize the significant role of biliary tract infection in the development of disseminated intravascular coagulation (DIC). Among 26 patients with biliary tract infection, 6 patients developed diffuse bleeding tendency (ecchymoses, gastrointestinal bleeding, hematuria, and bleeding from operative wounds, choledochostomies, and venipuncture sites. Supprative cholangitis occurred in all cases. The signs of multiorgan dysfunction were seen in most patients, including oliguria or anuria (3 patients), cardiac symptoms (2), respiratory distress (5), and mental confusion (4). Hypotension was present in five patients. Most patients showed marked coagulation defects characterized by thrombocytopenia, decreased fibrinogen and antithrombin III levels ($p<0.05$), decreased plasminogen levels ($p<0.02$), narrowing of the maximal amplitude in thrombelastograms, increase of fibrin degradation products ($p<0.05$), and increase of positive soluble fibrin monomer complexes. Five patients died from 10 days to 3 months after the biliary tract decompression. In two cases, postmortem examination revealed multiple fibrin thrombi in lungs and other organs. The remaining 20 patients showed no bleeding tendency but remarkable hypercoagulability with decreased fibinolytic activity. The development of DIC was more frequent in cases in which biliary tract decompression failed. These clinical, hematological, and pathological findings strongly suggest that the development of bleeding tendency in obstructive jaundice may be due to the occurrence of DIC, i.e., that hypercoagulability caused by the biliary tract infection is responsible.

0694 FUNCTION CHANGES OF THE SPHINCTER OF ODDI AFTER DIFFERENT TYPES OF VAGOTOMY. (Eng.) Schumann, Z.; Darup, K.; Gentsch, H. (Univ. Erlangen, Dept. Surgery, Nurnberg, W. Germany). *Chir. Gastroenterol.* 10(4):437-439; 1976.

Myoelectric changes in the papilla of Vater were studied in 24 dogs after truncal, selective, or parietal cell vagotomy. In six dogs that underwent truncal vagotomy, there was an initial decrease in tone in the sphincter of Oddi; this tone later increased and approached the initial basal level. The amplitude of the action potential was increased by 150 ± 10 μV per unit, and frequency was decreased to 72 Hz. The extrahepatic bile ducts appeared atonic and dilated. After selective vagotomy, the amplitude was similar to that in nonoperated controls; the frequency was 72 Hz. There were no changes in the electromyographic activity of the papilla of Vater in the dogs that underwent parietal cell vagotomy; the amplitude and frequency were 22 ± 5 μV/U and 100 Hz, resp., values identical with those of the controls. These results indicate that parietal cell vagotomy is the procedure of choice in the treatment of duodenal ulceration.

GENERAL

0717 ALIMENTARY TRACT MANIFESTATIONS OF MULTIPLE ENDOCRINE NEOPLASIA, TYPE 2b. (Eng.) Carney, J. A.; Hayles, A. B. (Mayo Clinic, Rochester, MN). *Mayo Clin. Proc.* 52(9):543-548; 1977.

Alimentary tract manifestations were found in all of 17 patients with multiple endocrine neoplasia, type 2b, and the cases of 7 patients are presented. The alimentary tract manifestations were important because (a) they were chronic; (b) they were severe and led to abdominal operation in 5 patients; (c) they antedated detection of the endocrine neoplasms in the syndrome in 16 patients (94%); and (d) they provided clinical clues that stimulated a search for thyroidal C-cell and adrenal medullary disease in 6 patients. The alimentary tract manifestations were diverse; the symptoms included constipation, diarrhea, difficulty with feeding, projectile vomiting, crampy abdominal pain, and loud borborygmi. Other findings included thickened lips, nodules on the anterior third of the tongue, abdominal distention, visible peristaltic waves, and roentgenographic evidence of megacolon or diverticulosis of the colon or of dilatation of the small intestine and stomach. Initial misinterpretation or failure to realize the significance of one or more of these alimentary tract manifestations led to suspicion of aganglionic megacolon (3 patients), malabsorption syndrome (2 patients), and tracheal ring (1 patient).

0718 IMMUNOGLOBULINS IN JEJUNAL MUCOSA AND SERUM FROM PATIENTS WITH DERMATITIS HERPETIFORMIS.

(Eng.) Baklien, K.; Fausa, O.; Thune, P. O.; Gjone, E. (Rikshospitalet, Oslo 1, Norway). *Scand. J. Gastroenterol.* 12(2):161-168; 1977.

The quantitative distribution of immunoglobulin (Ig)-producing cells was determined by paired immunohistochemistry in the proximal jejunal mucosa of 29 patients with dermatitis herpetiformis (DH). The specimens were categorized stereomicroscopically into three groups on the basis of mucosal abnormality. Compared with control subjects, the total number of Ig-producing cells in a defined "mucosal tissue unit" was raised by a factor of 1.4 in group I (normal or minor abnormality), but the class ratios remained normal. In group III (major abnormality), the total immunocyte number was raised 2.6 times; IgA, IgM, and IgG cells showed a 2.4-, 3.5-, and 5.1-fold increase, resp. Group II (intermediate abnormality) fell between the two other groups with regard to changes in immunocyte population. The local immunocyte pattern was very similar to that previously reported for celiac disease (CD) specimens with comparable mucosal abnormalities. There were few IgD cells, and there was no increase in these cells, compared with control levels. IgE cells were also infrequent, but they were more numerous than in control tissue. As in CD, staining for extracellular Ig in the lamina propria tended to be more intense than that in controls. Normal or increased staining for SC, IgA, and IgM in the crypt epithelium indicated a normal external transfer of these components. DH differed from CD in showing no significant increase in serum IgA level. Serum IgM was reduced in group III, and IgG was increased in group I.

0719 CONGENITAL CHLORIDE DIARRHOEA.

(Eng.) Holmberg, C.; Perheentupa, J.; Launiala, K.; Hallman, N. (Children's Hosp., Univ. Helsinki, Helsinki, Finland). *Arch. Dis. Child.* 52(4):255-267; 1977.

Clinical findings in 21 Finnish children with congenital chloride diarrhea are reported. All children were born 1-8 weeks prematurely. Hydramnios was present in all cases, and no meconium was seen; thus, the onset of diarrhea occurred *in utero*. Diarrhea or passing of large volumes of urine was noted on the first day of life, and the abdomen was usually large and distended. The abnormally large neonatal weight was associated with hypochloremia and hyponatremia. A few infants survived the neonatal period without adequate therapy, but later they developed hypochloremia, hypokalemia, and metabolic alkalosis associated with hyperaldosteronism. However, these conditions may be absent; therefore, diagnosis is based on a history of hydramnios and diarrhea and a fecal Cl^- concentration >90 mM. Lower fecal Cl^- concentrations were seen only in chronic hypochloremia, which is also associated with achloriduria. Adequate treatment consists of full continuous replacement of the fecal losses of water, NaCl, and KCl. These substances should be given i.v. in the early neonatal period; later, they can be given p.o., with meals. The electrolyte dose has to be adjusted to maintain normal serum concentrations, normal blood pH, and some chloriduria. This therapy prevents the renal lesions and the retarded growth and psychomotor development that were seen in children who were diagnosed late and in those who received inadequate replacement therapy. The watery diarrhea persists and increases slightly with age, although patients learn to live with their disease and to make an adequate social adjustment.

0720 SPECIAL O:K:H SEROTYPES AMONG ENTEROTOXIGENIC E. coli STRAINS FROM DIARRHEA IN ADULTS AND CHILDREN: OCCURRENCE OF THE CF (COLONIZATION FACTOR) ANTIGEN AND OF HEMAGGLUTINATING ABILITIES.

(Eng.) Orskov, I.; Orskov, F. (Collaborative Center for Reference and Res. on *Escherichia* [WHO], Statens Seruminstitut, Amager Blvd. 80, DK-2300 Copenhagen S, Denmark). *Medical Microbiol. Immunol. (Berl).* 163(2):99-110; 1977.

Countercurrent immunoelectrophoresis was used to determine polysaccharide K antigens in O:H serotypes among 77 enterotoxigenic *Escherichia coli* strains, including strains from human diarrhea. Members of each O:H serotype had the same type of K antigen and were characterized by a certain fermentation pattern. Some O:H serotypes had no K antigen. The serofermentative types defined were: O6:K15:H16, O8:K40:H9, O15:H11, O25:K7:H42, O25:K98:H^-, O78:H11, O78:H12, and O149:H10. Some strains of serotype O149:H10, which are suspected of being associated with foodborne infections, had K88 antigen. This serotype belongs to the group of strains causing diarrhea in swine. Colonization factor (CF), a pilus-like antigen that is plasmid-controlled and that endows the bacterial cells with an ability to colonize the intestine, was found only in human enterotoxigenic strains belonging to O group 78. In particular, CF was found in 17 of 77 enterotoxigenic strains, and all 17 belonged to O78:H11, O78:H12, or O78:H^-; CF was not found among 248 type O78 strains from sources other than human diarrhea. The presence of CF in type O78 strains was correlated with the presence of a mannose-resistant ability to cause agglutination of human RBC. An examination of the hemagglutinating ability of the other serotypes revealed that O25:K7:H42 strains were similar to the O78 strains in this respect.

0721 EPITHELIOID GERMINAL CENTERS: AN ACQUIRED IMMUNOLOGIC DEFICIT? (Eng.) Millikin, P. D. (Peoria-Tazewell Pathology Group, S.C., 5409 North Knoxville, Peoria, IL 61614). *Am. J. Clin. Pathol.* 67(6):545-549; 1977.

In an attempt to determine whether the fatal outcome of childhood infections associated with epithelioid germinal center abnormalities is related to an acquired immunologic deficit, the histologic structure of lymphoid tissue in cases of fatal infection is reviewed. Epithelioid germinal centers, completely devoid of the usual dark zone of rapidly dividing blast cells, were found in 16 infants and children, one of whom also had Reye's syndrome. In four additional cases, there was toxic follicle alteration, or massive necrosis of germinal center cells. Toxic follicle alteration and epithelioid change have been found in childhood infections and sudden infant death syndrome, and some evidence of a pathogenetic relationship between the two was found in this study. It is concluded that epithelioid change represents a definite pathologic alteration of germinal centers associated with total destruction of a whole population of cells. It probably represents an acutely acquired immunologic deficit and therefore may well contribute to the thus far uniformly fatal outcome of the associated diseases.

0722 ABDOMINAL TUBERCULOSIS: EXPERIENCES WITH 300 CASES. (Eng.) Bhansali, S. K. (81 Valentina Naoroji Gamadia Rd., Bombay 400 026, India). *Am. J. Gastroenterol.* 67(4):324-337; 1977.

Experience with 300 cases of surgically proven abdominal tuberculosis is reviewed. In 161 cases, the onset of illness was insidious; a definite lump was palpable in 96 of these patients. Acute manifestations were seen in 139 patients, with acute abdominal pain being the cardinal feature. Of the 139 patients who presented with acute manifestations, 92 presented with intestinal obstruction; roentgenologic studies detected fluid levels in the flat film of the abdomen in 91 of these 92 patients. Surgery was resorted to when complications were present, when diagnosis was in doubt, and when intrinsic intestinal disease was proved. Surgery was preceded by antituberculous drugs whenever possible. At surgery, the disease was found to involve the alimentary canal in 196 cases, with the small intestine being more frequently involved than the cecum and colon. In 104 cases, only the lymph nodes and/or the peritoneum were affected. Intestinal resection was performed in 101 cases. There were 22 operative fatalities, with 18 resulting after emergency operations. Significant postoperative complications were wound sepsis, bronchopulmonary complications, and fecal fistula. Death due to toxemia within 72 hr after surgery occurred in 15 patients. Positive histology was obtained in 229 cases, and 179 of these showed evidence of caseation. Caseation and peritoneal tubercles (103 cases) differentiated intestinal tuberculosis from Crohn's disease.

0723 A 44-YEAR EXPERIENCE WITH TUBERCULOUS ENTEROCOLITIS. (Eng.) Homan, W. P.; Grafe, W. R.; Dineen, P. (New York Hosp.-Cornell Medical Center, 525 E. 68th St., New York, NY 10021). *World J. Surg.* 1(2):245-250; 1977.

Thirty-one cases of intestinal tuberculosis, diagnosed between 1932 and 1975 at one hospital are reviewed, with particular reference to the impact of antituberculous chemotherapy on the outcome of the disease and to the role of surgery in diagnosis and treatment. The chest x-ray was 90% effective in demonstrating evidence of tuberculosis. However, since even on gross examination differentiation of intestinal tuberculosis from Crohn's disease or neoplasia may be impossible, surgical exploration is indicated when diagnosis is in doubt, and biopsy and culture of intraabdominal tissue should be performed for diagnostic purposes. The importance of instituting immediate therapy is emphasized by a 67% mortality rate in the prestreptomycin era and a 21% mortality rate in patients receiving appropriate drug therapy. Because of the success of chemotherapy, intestinal resection is seldom indicated, except in those cases in which scarring and stricture formation demand surgical relief of intestinal obstruction or in which the complications of fistula, hemorrhage, or perforation may occur.

0724 GASTRIC MUCOSA IN PATIENTS WITH RHEUMATOID ARTHRITIS TREATED WITH ANTI-INFLAMMATORY AGENTS. CLINICAL, RADIOLOGICAL, ENDOSCOPIC, PATHOLOGICAL AND ULTRASTRUCTURAL STUDY. (Fre.) Gaucher, A.; Serot, J. M.; Gaucher, P.; Rauber, G.; Grignon, G.; Pourel, J.; *et al.* (Hopital de Brabois, F 54500 Vandoeuvre-les-Nancy, France). *Nouv. Presse Med.* 5(41):2781-2784; 1976.

GENERAL

Regional Enteritis

0757 INTRAMURAL GANGLION CELL DEGENERATION IN INFLAMMATORY BOWEL DISEASE. (Eng.) Oehmichen, M.; Reifferscheid, P. (Institut fur Hirnforschung, Universitat Tubingen, Belthlestrasse 15, D-7400 Tubingen, W. Germany). *Digestion* 15(6):482-496; 1977.

Comparable histologic alterations of intramural nervous tissue were reported in various diseases of the small and large intestine. In six patients, an intestinal obstruction led to secondary intramural inflammation. The obstruction was induced by the spastic segment in Hirschsprung's disease (3 cases), by rectal atresia (2), and by postoperative ischemic damage to the intestinal wall (1). In four other patients, the inflammation was predominant, and it was due to necrotizing enterocolitis (1 case), membranous enteritis (1), and Crohn's disease (2). In all cases, various degrees of inflammatory lymphocytic infiltration were observed proximal to the obstruction. Other common alterations were splitting of nerve fibers and deteriorations of nerve cells (degenerative alterations) in the plexus myentericus, as well as hyperplasia and hyperchromasia of the ganglion cells, Schwann cell proliferation, and fibrosis in the nerve fibers (reactive alterations). Until now, these alterations were only observed in Chagas' disease and in ulcerative colitis, especially when these conditions were complicated by toxic megacolon. The neurodegenerative alterations in these diseases may be toxically induced.

0758 REGIONAL ILEITIS (CROHN'S DISEASE). I. KINETICS OF BILE ACID ABSORPTION IN THE PERFUSED ILEUM. (Eng.) Krag, E.; Krag, B. (Herlev Hosp., DK-2730 Copenhagen/Herlev, Denmark). *Scand. J. Gastroenterol.* 11(5):481-486; 1976.

Glycochenodeoxycholic acid (GCDC) absorption was studied by the steady state perfusion technique in the ileum of 11 patients with regional ileitis (Crohn's disease). Computerized absorption kinetics demonstrated a saturable transport system and a competitive absorption between conjugated bile acids, suggesting that GCDC is actively transported. At the time of the investigation, five patients had no diarrhea, whereas six had diarrhea, as defined by the amount of fecal output (>200 g/day). In the former group, the fecal bile acid excretion was low, and the ileal absorption of GCDC was high; the ileal absorption surface was judged to be large compared with that in the patients with diarrhea, on the basis of xylose absorption. In the patients with diarrhea, the fecal bile acid excretion was high, the ileal absorption of GCDC was low, and the ileal absorptive surface was small. It is concluded that malabsorption of bile acids in the ileum may be of significant physiological importance in the pathogenesis of diarrhea in patients with regional ileitis.

PREFACE

GASTROENTEROLOGY ABSTRACTS and CITATIONS is a publication of the National Institute of Arthritis, Metabolism and Digestive Diseases. This specialized information medium has been initiated to fill an existing great need in the field of gastroenterology and to assist the Institute in meeting its obligations to foster and support laboratory and clinical research into the nature, causes, and therapy of diseases of the gastrointestinal tract. Publication GASTROENTEROLOGY ABSTRACTS and CITATIONS makes available citations of all current papers relevant to this field from medical journals published throughout the world. Approximately one-third of the citations dealing with the major aspects of gastroenterology have accompanying abstracts.

The issuing of GASTROENTEROLOGY ABSTRACTS and CITATIONS under the auspices of the National Institute of Arthritis, Metabolism, and Digestive Diseases will provide a much needed current awareness tool to scientists and will facilitate greater integration of research and clinical efforts in this field. The number and great diversity of publications in the area of gastroenterology makes it imperative that an appropriate service be available to investigators and practitioners so that they may be apprised of progress with a minimum of delay. Our aim is to provide the readers with a readily systematized compilation of current published work. The publication will provide the greatest usefulness if these interested investigators will contribute their ideas and comments for consideration whenever possible.

GASTROENTEROLOGY ABSTRACTS and CITATIONS is published monthly and includes citations and abstracts from the biomedical world literature as they are currently received. In addition, yearly cumulated subject and author indexes are published.

This publication is available free to National Institutes of Health grantees and contractors working in the field of gastroenterology and libraries of medical schools. Requests from these qualified individuals to receive free copies of this publication must include their grant or contract number and the title of their project. These requests as well as address changes and other communications should be addressed to:

Scientific Communications Officer
Gastroenterology Abstracts and Citations
National Institute of Arthritis, Metabolism and Digestive Diseases
National Institutes of Health
Building 31, Room 9A-21
Bethesda, Maryland 20014

Other individuals and libraries may receive this publication by subscribing *directly* to the Superintendent of Documents, U.S. Government Printing Office, Washington, D.C. 20402. Subscription price per year in the United States and its possessions: $27.00 (this includes index issue); foreign, $6.75 additional. Single copy price is $1.90 domestic and $2.40 foreign. The index issue is $3.45 domestic and $4.35 foreign. Payment is required in advance, and check or money order should be made payable to the Superintendent of Documents.

DEPOSITORY

The Secretary of the Department of Health, Education, and Welfare has determined that the publication of this periodical is necessary in the transaction of the public business required by law of this Department. Use of funds for printing this periodical has been approved by the Director of the Office of Management and Budget through April 30, 1981.

For sale by the Superintendent of Documents, U.S. Government Printing Office, Washington, D.C. 20402. Subscription price per year in the United States and its possessions: $27.00 (this includes index issue); foreign, $6.75 additional. Single copy price is $1.90 domestic and $2.40 foreign. The index issue is $3.45 domestic and $4.35 foreign. Payment is required in advance, and check or money order should be made payable to the Superintendent of Documents.

NOTE

Journal names are abbreviated according to the list of abbreviations used by *Index Medicus*. For journals not covered by *Index Medicus*, the abbreviations (with some modifications) found in *International Standard ISO833, 1974*, are used. The two-letter state abbreviations are based on the United States Postal Service Code.

PRE-CLINICAL SCIENCES

MORPHOLOGY, CELLULAR STRUCTURE AND HISTOCHEMISTRY

0778 CYTOCHEMICAL STUDY OF INTESTINAL ENDOCRINE CELLS IN RABBIT FETUSES DURING IN VITRO INDUCED DEGENERATION AND DIFFERENTIATION. (Fre.)

Lefranc, G.; Pradal, G.; L'Hermite, A. L.; Andre, M. J.; Ducluzeau, A. (Laboratoire d'histologie et Embryologie, Faculte de Medecine, F-44 Nantes, France). *Histochemistry* 53(2):157-163; 1977.

In vitro culture of fragments of the intestinal mucosa of rabbit fetuses in solid media induces epithelial degeneration followed by regeneration. At the end of 3 days, degenerated necrotic cells sloughed off in the intestinal lumen and regenerating cells in contact with the chorion could be observed on the same histological section. The histochemical characteristics of the serotonin cells were studied and related to the stages of differentiation. The cells acquired successively the following characteristics: fluorescence induced by formaldehyde (FIF), then argyrophilia, then affinity for silver salts. *In vivo* studies have shown that FIF and argyrophilia appear simultaneously. These *in vitro* studies suggest an extra step in the differentiation of the serotonin-producing cells of the intestine that may exist *in vivo* but has not as yet been observed.

0779 ENDOCRINE CELLS IN THE HUMAN FETAL SMALL INTESTINE. (Eng.)

Moxey, P. C.; Trier, J. S. (Peter Bent Brigham Hosp., 721 Huntington Ave., Boston, MA 02115). *Cell Tissue Res.* 183(1): 33-50; 1977.

The time of appearance and ultrastructural features of enteroendocrine cells (EECs) were studied in the human fetal small intestine between 9 and 22 weeks of gestation. Thirteen distinctive EECs were identified in fetal small intestine. Two of these, not found in normal small gut, appeared within the stratified epithelium of the proximal small intestine at 9-10 weeks. They were arbitrarily termed "primitive" and "precursor" cells. As in all fetal EECs, the pale cytoplasm of the "primitive" cell contained a distinctive population of secretory granules (SGs). Primitive cell SGs averaged 200-330 nm; some had dense cores with lucent halos, while others were filled with a homogeneous dense or flocculent material. The SGs of the "precursor" cells were larger, averaging up to 1 µm in diameter, and their contents varied in electron density. A third group of cells not described in adult small bowel was arbitrarily termed "transitional" cells. These had two populations of SGs; one resembled the SGs of the "precursor" cells, and the other resembled the SGs of some of the specific adult type EECs. Transitional enterochromaffin (EC), S, I, and G cells were seen. In addition, mature appearing EC, S, G, I, L, D, and D_1 cells were identified by 12 weeks of gestation. The "primitive," "precursor," and "transitional" cells may represent sequential developmental precursors of adult type EECs.

0780 RABBIT ILEAL MUCOSA EXPOSED TO FATTY ACIDS, BILE ACIDS, AND OTHER SECRETAGOGUES: SCANNING ELECTRON MICROSCOPIC APPEARANCES. (Eng.)

Gaginella, T. S.; Lewis, J. C.; Phillips, S. F. (Coll. Pharmacy, Ohio State Univ., Columbus, OH 43210). *Am. J. Dig. Dis.* 22(9):781-790; 1977.

Segments of rabbit ileum were examined by scanning electron microscopy (SEM) after exposure to various compounds known to stimulate small intestinal fluid secretion. After perfusion with 10 mM ricinoleate, striking changes were observed at villus tips and on the apicolateral surfaces of villi; erosions at tips were confirmed by light microscopy of the same pieces of tissue examined by SEM. The apicolateral surfaces of the villi had a "cracked clay" appearance. The appearances after ricinoleate were reversed in part during perfusion with control buffer for 2 hr. Statistical comparisons between control perfused, treated, and reversal tissues showed that the "damage" produced by ricinoleate, and its reversal, was statistically significant. Tissues treated with other intestinal secretagogues, oleic acid (10 mM), deoxycholic acid (4 mM), cholic acid (4 mM), dioctyl sodium sulfosuccinate (6 mM), and cholera toxin (1 µg/ml) also showed surface changes by SEM. Sodium oleate and sodium deoxycholate produced villus tip changes, dioctyl sodium sulfosuccinate and sodium cholate resulted in the "cracked clay" pattern, and cholera toxin produced both changes. Fluid secretion, produced by mannitol was not associated with "damage." Structural changes of the mucosal surface after exposure to intestinal secretagogues should be considered as one possible mechanism of impaired fluid transport.

0781 COLONIC MUCOSAL ATROPHY INDUCED BY A LIQUID ELEMENTAL DIET IN RATS. (Eng.)

Janne, P.; Carpentier, Y.; Willems, G. (Hopital Saint-Pierre, rue Haute 322, B. 1000 Brussels, Belgium). *Am. J. Dig. Dis.* 22(9):808-812; 1977.

The effect of feeding a liquid elemental diet (Vivonex®) for 4 weeks on the weight, the total crypt cell population, and the proliferation parameters of the colon was studied in male Wistar rats. Both mitotic activity and DNA synthesis activity were decreased ($p<0.01$) in the colonic mucosa during the administration of the diet, in comparison with that in controls. The weight of the colon was decreased ($p<0.01$) from the first week of treatment. After 4 weeks, a 75% decrease in the cell population of mucosal glands was observed, indicating that there had been considerable atrophy of the colonic mucosa. This atrophy was probably mediated by a reduction in the proliferative activity of the stem cells in the mucosal glands.

0782 MORPHOLOGY OF THE ISOLATED OXYNTIC CELL AND SOME PHYSIOLOGICAL PARAMETERS. (Eng.)

Ito, S.; Munro, D. R.; Schofield, G. C. (Harvard Medical Sch., Boston, MA 02115). *Gastroenterology* 73(4):887-898; 1977.

The morphology of the isolated mouse oxyntic cell is described and compared with that of the intact stomach. Isolated oxyntic cells adopt a variety of morphological configurations. Some cells retain their polarity, so that a portion of the surface membrane is formed by laterobasal membrane and the remainder by luminal surface membrane with secretory or intracellular canaliculi opening to the outer surface. Other cells present a smooth outer surface and a completely internalized canaliculus. There are also oxyntic cells in which the whole surface membrane is covered with numerous microvilli resembling those of the luminal surface of oxyntic cells *in situ*. In cells where both laterobasal and luminal membrane can be distinguished, a junctional region that shows an intermixing of these two types of surface membranes is seen. Intracellular canaliculi of isolated oxyntic cells may be either distended and lined by microvilli or virtually collapsed and occluded by numerous microvilli. Evidence of functional activity by isolated oxyntic cells includes a small but consistent movement of chloride toward the cathode when a polarizing potential is applied to isolated cells forming a monolayer. Uptake studies with ^{3}H-leucine indicate that isolated oxyntic cells avidly incorporate this substrate and apparently metabolize it. Current studies on respiration by isolated oxyntic cells reveal a doubling of oxygen consumption when succinate is added to the incubating medium. However, oxygen utilization by isolated cells from acetazolamide-inhibited mice is only one-half that of nontreated control cells.

0783 FROG GASTRIC TUBULAR CELLS: ISOLATION, CULTURE, AND SOME PROPERTIES. (Eng.)

Kasbekar, D. K.; Blumenthal, G. H. (Georgetown Univ. Sch. Medicine and Dentistry, Washington, DC 20007). *Gastroenterology* 73(4):881-886; 1977.

The methods used for obtaining primary cultures of the gastric tubular cells from *Rana catesbeiana*, the maintenance of their differentiated state under culture conditions of several weeks, and some of their properties are described. The problem of microbial contamination in the amphibian cells was overcome by incubating the cells in medium containing an antibiotic mixture. During the first few days after isolation and culture, cell surface damage was manifested by enhanced leakage of intracellular pepsinogen and a lack of response to known gastric secretagogues with respect to pepsinogen release and respiration. After several days in culture, the cellular pepsinogen levels increased slightly but significantly, and the spontaneous loss of pepsinogen from the cells showed a marked decline, indicating repair of the initial membrane or surface damage. The intact cells possessed *p*-nitrophenylphosphatase activity. After several days in culture, the respiratory activity became sensitive to the serum concentrations of the culture medium and was relatively stable. Antibiotics used in establishing primary cultures reversibly inhibited respiration and pepsinogen synthesis. A variable response to the gastric secretagogues was observed with regard to respiratory and pepsinogen secretory activities, whereas the *p*-nitrophenylphosphatase activity remained unaffected. There was no indication that the cells divided under the present culture conditions. Although these cells did not attach firmly to the surface of plastic or glass culture flasks, preliminary evidence indicates that collagen gel may provide an appropriate matrix for cell attachment. Further studies with a reconstituted epithelium comprised of a homogeneous gastric tubular cell population are indicated.

0784 TERMINATION AND LUMEN OF THE HEPATO-PANCREATIC EXCRETORY DUCTS. A MORPHOMETRI STUDY. (Ger.)

Muller, M.; Putzke, H. P. (Institut fur Allgemeine und Spezielle Pathologie, Wilhelm-Pieck-Universitat, Strempelstrasse 14, DDR-25 Rostock, E. Germany). *Dtsch. Z. Verdau. Stoffwechselkr.* 37(1):1-6; 1977.

The termination and lumen of the hepatopancreatic excretory system was studied in 200 autopsy cases. Common papilla was found in 183 cases and common pancreaticobiliary duct in 141. The hepatopancreati excretory system had type y termination in 70.5% of all cases, type v in 21%, and type u in 8.5%. The average length of the ampulla of Vater was 5.4 mm. The diameter of the pancreatic duct was 7.3 mm in the head of the pancreas, 5.7 mm in the body, and 2.5 mm in the tail. The diameter of the choledochal duct was 3.5 mm at its entry into the ampulla of Vater and into the duodenum, 12 mm at 2-cm distance proximally, and 16.5 mm at 6-cm distance proximally. No correlation was found between the lumen of the pancreatic duct and the type of the termination, but the size of the lumen increased with age.

0785 ULTRASTRUCTURAL STUDY OF COLONIC MUCOSA INVASION BY E. histolytica. (Spa.)

Trevino, N.; Cruz de Lavin, E.; Tanimoto-Weki, M. (Centro Medical Nacional, Instituto Mexican del Seguro Social, Av. Cuahtemoc 330, Mexico 7, D.F.). *Arch. Invest. Med. (Mex.)* 8(1):71-83; 1977.

0786 ANATOMY OF THE ANORECTAL SPHINCTER AND ITS SURGICAL IMPLICATIONS. (Por.)

Matos, D.; Werneck Lima, J.; De Oliveira, E. (Hospital Sao Paulo, Sao Paulo, Brazil). *Bol. Sanat. Sao Lucas* 38(4):147-160; 1977.

0787 THE EFFECT OF ETHANOL ON THE ULTRASTRUCTUR OF ACINI OF THE PANCREAS. (Rus.)

Podolsk A. E. (N. V. Sklifovsky Res. Inst. Emergency Aid, Moscow, USSR). *Biull. Eksp. Biol. Med.* 83(3):377-379; 1977.

0788 STRUCTURE AND INNERVATION OF THE CHOLEDOCHO DUODENAL JUNCTION. (Eng.) Kyosola, K. (Dept. Anatomy, Univ. Helsinki, Helsinki, Finland). *Ann. Chir. Gynaecol.* 65(Suppl. 192):1-135; 1976.

0789 ENDOCRINE CELLS IN THE NORMAL HUMAN COLON AND RECTUM: ULTRASTRUCTURAL STUDY [Abstract]. (Eng.) Cristina, M. L.; Lehy, T.; Zeitoun, P. (INSERM U-10, Hopital Bichat, 75877 Paris, Cedex 18, France). *Digestion* 16(1/2): 207-208; 1977.

ABSORPTION - EXCRETION - TRANSPORT

0790 POSTPRANDIAL SERUM BILE ACIDS IN HEALTHY MAN: EVIDENCE FOR DIFFERENCES IN ABSORPTIVE PATTERN BETWEEN INDIVIDUAL BILE ACIDS. (Eng.) Angelin, B.; Bjorkhem, I. (Dept. Medicine, Serafimerlasarettet, S-112 83 Stockholm, Sweden). *Gut* 18(8):606-609; 1977.

The hypothesis was tested that substantial dihydroxy bile acid absorption in the proximal small intestine is responsible for observed increases in the cholic acid (C)/chenodeoxycholic acid (CD) and C/deoxycholic acid (D) ratios in intestinal aspirates along the proximal intestine. The serum concentrations of C, CD, and D before and after a standardized meal were determined in five healthy women using a highly specific and accurate gas chromatographic-mass spectrometric technique. The C level rose significantly 60 min after the meal, reached a peak after 90 min, and had returned to the original level after 150 min. In contrast, the serum concentrations of CD and D displayed a significant rise by 30 min, reached a peak after 90 min, but had not returned to fasting levels after 150 min. The results suggest that there is considerable absorption of dihydroxy bile acids in the proximal small intestine in man.

0791 TRANSPORT OF α-AMYLASE ACROSS THE BASOLATERAL MEMBRANE OF THE PANCREATIC ACINAR CELL. (Eng.) Isenman, L. D.; Rothman, S. S. (Dept. Physiology, Univ. California, San Francisco, CA 94143). *Proc. Natl. Acad. Sci.* 74(9): 4068-4072; 1977.

The flux of α-amylase (1,4-α-D-glucan glucanohydrolase; EC 3.2.1.1) across the basolateral membrane of the acinar cell was measured in the cell-to-bath direction using the whole rabbit pancreas in organ culture. This *in vitro* preparation is polarized so that apical and basolateral secretions can be collected separately. The unstimulated amylase flux from cell to bath was substantial at the initial rate (approximately 3 times the concurrent apical flux). With time, bath amylase approached a steady-state concentration, suggesting an equilibrating process. During the same time interval, ductal amylase secretion remained constant. At the steady state, the amylase concentration in the bath was at least an order of magnitude less than its ductal concentration. Hourly replacement of bathing medium reproduced the initial rate of amylase release into the bath for five consecutive hours. Pancreozymin (cholecystokinin) did not alter the steady-state bath amylase content, although it greatly augmented ductal amylase secretion. In contrast, acetyl-β-methyl-choline chloride greatly increased both the flux from the cell to bath and the ductal secretion of amylase. The results indicate a natural bidirectional permeability of the basolateral membrane to digestive enzyme. The results also support evidence previously obtained, which suggested that such a permeability might exist and that these fluxes are all related by a cytoplasmic pool (or pools) of digestive enzyme that acts as both a source of and a repository for enzyme crossing the membrane.

0792 ABSORPTION OF HORSERADISH PEROXIDASE BY NEONATAL PIG INTESTINAL EPITHELIUM. EFFECT OF Escherichia coli (O55B5) ON ABSORPTION. (Eng.) Staley, T. E. (Coll. Veterinary Medicine, Stillwater, OK 74074). *Am. J. Vet. Res.* 38(9): 1307-1314; 1977.

The pathway of macromolecular transport through the neonatal pig small intestinal epithelium following the adherence of *Escherichia coli* to the apical ends of enterocytes (monocontamination) was examined and compared with transport in unexposed (sterile) controls, utilizing the cytochemical marker horseradish peroxidase (HRP). In control animals, the marker was adsorbed to apical microvilli inside apical tubules and filling cytoplasmic vacuoles of the enterocytes. Extracellular absorbed marker assumed a spherical appearance within the subepithelial spaces but was dispersed within the capillary lumens. Uptake of HRP into the enterocyte occurred in 48-hr-old neonatal pigs, but transport into the circulation was not observed. Exposure to *E. coli* was accomplished by the intragastric administration of about 1 g of organisms/kg body weight. Adherence of *E. coli* to the surface of the ileal enterocyte did not totally inhibit HRP uptake. The *E. coli* that adhered to the surface of the enterocyte or that were seen within intercellular vacuoles appeared to be static since they were not involved in the transepithelial migration of envacuolated HRP.

0793 STUDIES ON TRANSLOCATION OF IMMUNOGLOBULINS ACROSS INTESTINAL EPITHELIUM. I. IMPROVEMENTS IN THE PEROXIDASE-LABELED ANTIBODY METHOD FOR APPLICATION TO STUDY OF HUMAN INTESTINAL MUCOSA. (Eng.) Isobe, Y.; Chen, S. T.; Nakane, P. K.; Brown, W. R. (Denver Veterans Admin. Hosp., 1055 Clermont St., Denver, CO 80220). *Acta Histochem. Cytochem.* 10(2):161-171; 1977.

The peroxidase-labeled antibody method was adapted for the localization of immunoglobulins and the secretory component in human intestinal mucosa by light and electron microscopy. Modifications of the method included (1) the use of digitonin in the first wash step of tissues fixed in periodate-lysine-paraformaldehyde, (2) double coating of glass slides with gelatin and egg albumin before application of cryostat sections, and (3) inactivation of endogenous peroxidase by periodic acid treatment of cryostat sections. With these improvements, tissue morphology was well preserved, antigenicity of immunoglobulins and the secretory component was retained, penetration of labeled antibodies into cellular compartments was complete, and confusion at the light microscopic level between peroxidase-containing cells and cells stained with peroxidase-labeled antibodies was avoided.

0794 EFFECTS OF 1α,25-,24r,25- AND 1α,24r,25-HYDROXYLATED METABOLITES OF VITAMIN D$_3$ ON CALCIUM AND PHOSPHATE ABSORPTION BY DUODENUM FROM INTACT AND NEPHRECTOMIZED RATS. (Eng.) Walling, M. W.; Hartenbower, D. L.; Coburn, J. W.; Norman, A. W. (Veterans Admin. Wadsworth Hosp. Center, Riverside, CA 92502). *Arch. Biochem. Biophys.* 182(1):251-257; 1977.

The effects of 1α,25-dihydroxyvitamin D$_3$, 24*R*,25-dihydroxyvitamin D$_3$, and 1α,24*R*,25-trihydroxyvitamin D$_3$ on active calcium and phosphate transport by rat duodenum were studied in sham-operated and bilaterally nephrectomized vitamin D-deficient rats. Both 1α,25-dihydroxy- and 1α,24*R*,25-trihydroxyvitamin D$_3$ markedly stimulated calcium and phosphate absorption with similar effects in sham-operated and nephrectomized rats. A 10-fold higher dose of 24*R*,25-dihydroxyvitamin D$_3$ was required for an equivalent stimulation of absorption in sham-operated rats, and this compound had no effect on duodena from nephrectomized rats. These data provide the first evidence that 24*R*,25-dihydroxy- and 1α,24*R*,25-trihydroxyvitamin D$_3$ can stimulate the active intestinal absorption of phosphate. The lack of response to 24*R*,25-dihydroxyvitamin D$_3$ in nephrectomized rats confirms prior results that indicated that renal metabolism of this secosteroid to 1α,24,25-trihydroxyvitamin D$_3$ is required for biological activity. These experiments provide a simple bioassay technique that apparently reflects the changes in duodenal calcium and phosphate absorption that occur under more rigorous short-circuited conditions and, in particular, can be used for screening putative 1α-hydroxyl analogs of vitamin D in nephrectomized rats.

0795 INTRACELLULAR IRON TRANSPORT IN RAT INTESTINAL EPITHELIUM: BIOCHEMICAL AND ULTRASTRUCTURAL OBSERVATIONS. (Eng.) Humphrys, J.; Walpole, B.; Worwood, M. (Welsh Natl. Sch. Medicine, Heath Park, Cardiff CF4 4XW, Wales). *Br. J. Haematol.* 36(2):209-217; 1977.

Iron absorption by the intestinal epithelial cells was studied in male Wistar rats, using differential centrifugation of mucosal homogenates and electron microscope autoradiography. The maximum concentration of ^{55}Fe (62% of ^{55}Fe in the homogenate) was found 1 hr after intragastric administration. The maximum concentration of ^{55}Fe was found in the mitochondrial fraction after 18 hr. The mitochondrial, lysosomal, and microsomal fractions were examined by electron microscopy after autoradiography. One hour after the administration of ^{55}Fe, grains were associated with all the cell organelles, but in particular with microsomal vesicles. Eighteen hours after ^{55}Fe administration, the majority of the grains were associated with mitochondria; approximately 3% of the mitochondria contained one or more grains 18 hr after administration, demonstrating that the radioactivity in the mitochondrial fraction was associated with mitochondria and not with the other organelles contaminating this fraction. Sections of small intestine were taken 10, 20, and 30 cm from the pylorus. One hour after ^{55}Fe feeding, grains were found over the brush border, terminal web, and lateral cell membrane in the segment 10 cm from the pylorus. Thirty-two percent of the grains were found in the supranuclear regions of cells but were not associated with any particular membranes. At 20 cm, fewer grains were found, but a higher proportion were seen over the brush border and terminal web and a lower proportion over the lateral cell membrane. At 30 cm even fewer grains were seen, and these were distributed throughout the cell constituents. Eighteen hours after iron administration, few grains were present in the 10-cm segment. More were found in the 20-cm segment, 34% being located over mitochondria. The 30-cm segment showed many grains concentrated over mitochondria, endoplasmic reticulum, and ribosomes. The results suggest that mitochondria play a quantitatively significant role in iron metabolism within the epithelial cell but do not take part in the transport of iron across the cell during iron absorption.

0796 THE AGE-DEPENDENCE OF INTESTINAL ABSORPTION USING D-XYLOSE AS AN EXAMPLE. (Eng.) Heimann, G.; Roth, B.; Gladtke, E. (Children's Hosp., Joseph-Stelzmann-Strasse 9, D-5000 Koln 41, W. Germany). *Eur. J. Pediatr.* 124(4):285-294; 1977.

The effects of age and of changes in intestinal motility on absorption were studied in 40 infants. The serum concentrations of D-xylose were measured from capillary blood samples up to 300 min after the p.o. administration of D-xylose (0.5 g/kg). The absorption kinetics were calculated by a digital computer program. Infants up to the age of 2 months had lower maximal serum concentrations compared to older infants, because of a larger volume of distribution. The rate constant of invasion (k_1), which serves as a measure for the rate of intestinal absorption, and the rate constant of elimination (k_2) were significantly lower in infants up to the age of 2 months compared to older infants. The quotient of k_1/k_2 was independent of age. The time it took to reach maximal serum concentration was significantly longer in the young infants. The administration of metoclopramide (0.5 mg/kg) simultaneously with D-xylose demonstrated that the slower motility of the gastrointestinal tract in newborns and young infants is not exclusively responsible for the slower rate of D-xylose absorption. Experiments in which 26 infants received D-xylose (0.3 or 0.5 g) suggested that absorption involves saturation kinetics.

0797 ABSORPTION, AND EFFECT ON GASTRIC MUCOSA, OF BUFFERED AND NON-BUFFERED TABLETS OF ACETYLSALICYLIC ACID.

(Eng.) Linnoila, M.; Lehtola, J. (Duke Univ. Medical Center, Box 2921, Durham, NC 27710). *Int. J. Clin. Pharmacol. Biopharm.* 15(2):61-64; 1977.

The effects of buffered and nonbuffered acetylsalicylic acid tablets on the gastric mucosa and on gastric distress were investigated in 12 healthy subjects and in 42 rheumatoid arthritic patients, resp. The 12 healthy subjects received either acetylsalicylic acid (500 mg), acetylsalicylic acid buffered with magnesium oxide (175 mg), or acetylsalicylic acid buffered with magnesium oxide (100 mg) and aluminum aminoacetate (75 mg). One hour after the administration of the tablets, the acetylsalicylic acid level in the serum was significantly higher for the nonbuffered preparation than for the buffered preparation. Two hours after administration, this situation was reversed. However, the absolute means at any point in time differed by less than 2 µg. The serum salicylic acid levels were significantly higher 30, 60, and 90 min after the administration of the tablets buffered with magnesium oxide than after the other two types of tablets ($p<0.05$). In six healthy subjects in whom gastroscopy was carried out before and after 8 days of treatment with the preparations, gastric mucosal damage tended to be milder after the preparation buffered with magnesium oxide than after the nonbuffered preparation. Subjective feeling of gastric distress was observed in the 42 arthritic patients as often after buffered tablets as after nonbuffered tablets. These studies show that the absorption of salicylic acid is not affected in clinically significant amounts by buffering the tablets.

0798 THE DISPOSITION OF RADIOACTIVITY AFTER ADMINISTRATION OF THE ANTHELMINTHIC METHYL-^{14}C-5-CYCLOPROPYLCARBONYL-2-BENZIMIDAZOLE CARBAMATE (CICLOBENDAZOLE) TO RATS AND DOGS.

(Eng.) Brodie, R. R.; Mayo, B. C.; Chasseaud, L. F.; Hawkins, D. R. (Dept. Metabolism and Pharmacokinetics, Huntingdon Res. Center, Huntingdon, England). *Drug Res.* 27 (3):593-598; 1977.

The disposition of radioactivity was studied in rats and dogs after administration of a new anthelmintic agent, ^{14}C-labeled methyl-5-cyclopropylcarbonyl-2-benzimidazole carbamate (^{14}C-ciclobendazole). After a p.o. dose of ^{14}C-ciclobendazole (4 mg/kg) to rats, about 70% and 20% of the dose was excreted in the feces and urine, resp., during 2 days. Bile duct cannulated rats excreted about 80% of the dose in 48-hr bile, about 2% in the feces, and about 10% in the urine, showing that the p.o. dose was well absorbed and that some enterohepatic circulation probably occurred. The excretion of radioactivity in the bile was less after i.v. administration. A p.o. dose of ^{14}C-ciclobendazole (4 mg/kg) to dogs was mainly eliminated during 2 days with about 80% of the dose in the feces and only about 10% in the urine. Anesthetized bile duct cannulated dogs excreted between 26% and 35% of a p.o. dose in the bile during 24 hr and up to 58% was absorbed at this time. There was no unusual accumulation or localization of radioactivity in the tissues of rats or dogs following single or multiple p.o. doses of the drug. The highest concentrations were present in the intestinal tract, liver, and kidneys. After p.o. administration of ^{14}C-ciclobendazole to rats at three different dose levels (4, 40, and 400 mg/kg), peak plasma levels occurred at 15-30 min and declined with similar half-lives (about 20 hr). Ciclobendazole absorption was probably dose-dependent, a lower proportion probably being absorbed at higher doses. After repeated daily p.o. dosing with ^{14}C-ciclobendazole (4 mg/kg), there were no significant changes in either the daily plasma concentrations or the biological half-life measured after the last dose, indicating that ciclobendazole probably did not induce or inhibit its own metabolism.

0799 ABSORPTION OF ^{14}C-BUMADIZONE-Ca AND ^{14}C-PHENYLBUTAZONE IN ISOLATED INTESTINAL SEGMENTS IN VITRO AND TIED-OFF GASTROINTESTINAL SECTIONS IN VIVO OF RATS AND GUINEA PIGS.

(Eng.) Seebald, H.; Forth, W. (Lehrstuhl fur Pharmakologie und Toxikologie, Ruhr Universitat, Postfach 10 21 48, D-4630 Bochum, W. Germany). *Drug Res.* 27(1):624-635; 1977.

The absorption of butylmalonic acid mono(1,2-diphenylhydrazide) (bumadizone) and its condensation product was investigated in intestinal segments of rats and guinea pigs *in vitro* and *in vivo*. ^{14}C-labeled bumadizone-Ca and phenylbutazone were administered. In isolated jejunal segments of rats and guinea pigs *in vitro*, the transfer and the uptake of bumadizone by tissue was proportional to the concentration administered on the mucosal side. Bumadizone (320 nmol/ml) slightly decreased the absorption of water and glucose. Phenylbutazone inhibited the absorption of water and glucose by rat jejunal segments at 174 nmol/ml or greater. Transfer and uptake of phenylbutazone by tissue was proportional only up to 174 nmol/ml. Beyond this concentration they decreased. In guinea pigs, transfer was only one-fourth, and uptake by tissue only one-half of that in rat jejunal segments. The *in vivo* rat jejunum was found to be the main site of absorption of both bumadizone and phenylbutazone. Absorption was nearly complete within 1 hr after administering a dose of 0.64 μmol. In guinea pigs it was incomplete and was only one-fourth to one-third of that in rats. In the stomach, ileum, and colon, 1.5 to 3 times as much phenylbutazone was absorbed, as compared with bumadizone. Due to higher solubility in aqueous fluids, the availability of bumadizone-Ca for absorption exceeded that of phenylbutazone (1.62-97.2 μmol). In experiments with isolated jejunal segments of rats and guinea pigs *in vitro*, the capability of the intestinal tissue to produce phenylbutazone from bumadizone was demonstrated. Within 2 hr, nearly 20% of the ^{14}C-bumadizone was converted into phenylbutazone in both rat and guinea pig segments after the administration of bumadizone (16 μmol/ml).

0800 QUANTITATIVE STUDIES IN VITRO ON UPTAKE AND ESTERIFICATION OF PALMITATE INTO HUMAN AND RAT JEJUNAL MUCOSA. (Eng.) Sueur, R.; Cerf, M.; Di Costanzo, G.; Debray, C. (Hopital Bichat, Universite Paris VII, 170, Boulevard Ney, F-75877 Paris Cedex 18, France). *Digestion* 15(1): 34-42; 1977.

Quantitative incorporation and esterification of (9-10) ^{3}H-palmitate into human jejunal mucosa was measured *in vitro* to develop a technique for the determination of the esterifying capacity of the human intestinal mucosa sufficiently reliable to be applied semi-routinely in various pathological conditions. The results of the study were compared with results obtained in everted rat intestinal rings. Rat everted jejunal segments and jejunal biopsies from six normal subjects and two patients with adult celiac disease were incubated at 37 C in 4 ml of micellar solution (10 μM/ml sodium taurocholate, 3.6 μM/ml labeled palmitic acid, and 5 μM/ml glucose made up in Krebs-Ringer phosphate buffer, pH 7.4, Ca^{2+} omitted). Palmitate incorporation into diglyceride (DG) in the rat was higher than that into triglyceride (TG) with a TG:DG ratio lower than 1. Incorporation into cholesterol esters (CE) and phospholipid (PL) was low. There was a low but significant incorporation into monoglyceride (MG). Free fatty acid (FFA) uptake was high. In human jejunum, palmitate incorporation into CE, PL, and MG was low, reaching apparently a steady state by 5 min of incubation. Incorporation into TG was high, with a TG:DG ratio of about 3:1. Uptake into FFA was lower in man than in the rat, although the dispersion of the results was great. In the patients with celiac disease, the uptake into FFA was similar to that in the normal subjects. The incorporation of palmitate into TG and DG was increased with a TG:DG ratio below 2:1. The incorporation into TG was increased by the addition of monoolein into the incubation medium, but the total palmitate uptake was unchanged.

0801 ABSORPTION OF PHARMACOLOGIC DOSES OF ZINC. (Eng.) Oelshlegel, F. J.; Brewer, G. J. (Univ. Mississippi Medical Center, Jackson, MS 39216). *Prog. Clin. Biol. Res.* 14:299-311; 1977.

Absorption of orally administered zinc in the form of zinc sulfate was studied in fasting normal subjects. Assays of blood taken 0-4 hr after a 110-mg dose of zinc sulfate (providing 25 mg zinc) demonstrated that zinc absorption varies greatly in individuals. Varying the doses from 12.5 mg to 50 mg of zinc demonstrated that the smaller dose is more efficiently absorbed. Also, to maintain elevated plasma levels of zinc, doses of zinc should not be administered more than 4 hr apart. Since zinc sulfate is not well tolerated, zinc was also administered in the form of acetate and carbonate salts. Plasma levels of zinc were identical after administration of 25 mg zinc as the acetate or as the sulfate, but significantly lower ($p<0.05$) after the carbonate than after the sulfate. The effect of a number of foods (including hamburger on a bun, celery, lemon, coffee, and milk) ingested with the zinc sulfate on plasma zinc levels was studied. Most foods inhibited zinc absorption with the exception of bacon, hamburger meat, and, possibly, soft drinks, tea, and apples. Apparently, many dietary components such as fiber, phytic acid, and calcium block zinc absorption and may lead to zinc deficiencies.

MOTILITY

0819 ROLE OF GASTRIN AND OTHER GASTROINTESTINAL HORMONES IN THE PATHOPHYSIOLOGY OF ACHALASIA OF THE ESOPHAGUS. (Eng.) Santoki, O. (Yamaguchi Univ. Sch. Medicine, Ube, Yamaguchi, 755, Japan). *Arch. Jpn. Chir.* 46(2):88-112; 1977.

The effects of gastrin, secretin, cholecystokinin-pancreozymin (CCK-PZ), and Mecholyl on the lower esophageal sphincter pressure (LESP) were investigated in normal dogs, dogs with experimental achalasia, and in seven patients with achalasia. Achalasia was produced in the dogs by the injection of a 5% phenol solution into the muscular layers of the lower esophagus. The i.v. administration of tetragastrin (0.5, 1.0, 2.0, 5.0, 7.5, and 10.0 μg/kg) in these dogs produced a dose-dependent increase in the LESP; this curve shifted to the left in comparison with that in normal dogs, with each dose of tetragastrin. After the administration of 5.0 μg/kg of tetragastrin in 10 dogs with achalasia and 9 normal dogs, the LESP increased from a mean resting pressure of 8.4 ± 0.50 cm H_2O to 65.0 ± 3.67 cm H_2O in the dogs with achalasia, while that in the normal dogs increased from a resting pressure of 7.0 ± 0.83 cm H_2O to 40.1 ± 2.33 cm H_2O. The pressure change in response to tetragastrin in the dogs with achalasia was thus significantly greater than that in the normal dogs ($p<0.01$). The i.v. injection of secretin (5 CHRU/kg/5 min) had no significant effect on the resting LESP in normal and dogs with achalasia. The increase in LESP seen after tetragastrin was inhibited by a background dose of secretin in both normal and in dogs with achalasia. However, the percent reduction in the dogs with achalasia was not significantly different from that in the normal dogs, suggesting that the effect of secretin was not related to the destruction or degeneration of Auerbach's plexus. The injection of CCK-PZ (2.5 CHRU/kg, i.v.) increased the LESP in both normal and dogs with achalasia, and the response was significantly greater in the latter. The i.m. injection of Mecholyl (10 mg) produced an increase of 29.3 ± 2.75 cm H_2O in the normal dogs and an increase of 72.4 ± 3.80 cm H_2O in the dogs with achalasia ($p<0.01$). The gastrin levels were high in dogs treated with Mecholyl, suggesting that the LESP response may be partially mediated by the release of endogenous gastrin. In the human patients, the LESP increased significantly in response to 5 μg/kg of tetragastrin. This finding indicates that the LESP response to tetragastrin is useful in the preoperative diagnosis of achalasia.

0820 THE EFFECTS OF TRANSECTIONS ON THE BASIC ELECTRICAL RHYTHM IN THE CANINE JEJUNUM.

(Eng.) Mendel, C.; Pousse, A.; Dauchel, J.; Schang, J. C.; Grentier, J. F. (Unite de Recherche 61 de l'INSERM, Strasbourg-Hautepierre, France). *Eur. Surg. Res.* 8(6):528-535; 1976.

The effects of transection on the electrophysiology of the canine jejunum were studied. The basic electrical rhythm (BER) was studied *in situ* in 14 anesthetized dogs by the means of six monopolar electrodes. The BER frequency was measured in the intact intestine and after proximal and distal transections of the gut 5 cm apart from the electrodes. No significant differences were found between the BER frequencies recorded by each electrode, demonstrating the existence of a frequency plateau that remained after each transection. In the intact intestine the frequency in the plateau was 13.2 ± 0.3 cycles per minute (cpm). After the proximal transection, this frequency dropped to 12.0 ± 0.4 cpm ($p<0.05$) and, after the distal transection, it dropped to 10.9 ± 0.4 cpm ($p<0.05$). This last frequency change shows the influence of the distal intestine on the electrical behavior of the jejunum.

0821 GASTRIC EMPTYING AND SECRETION IN THE RHESUS MONKEY.

(Eng.) Dubois, A.; Natelson, B. H.; van Eerdewegh, P.; Gardner, J. D. (Natl. Inst. Arthritis, Metabolism, and Digestive Diseases, Bethesda, MD 20014). *Am. J. Physiol.* 232(2):E186-E192; 1977.

The volume and composition of the gastric contents as well as the rates of gastric emptying and gastric secretion were studied in the intact stomachs of eight conscious chair-adapted rhesus monkeys after fasting and after a liquid meal to investigate the physiologic variables that regulate gastric emptying and gastric secretion. Esophagotomies were prepared after 3 weeks of chair-adaptation, and experiments were begun 2-3 weeks later. Liquid meals (100 ml) were administered through a double-lumen sump tube passed into the stomach. Periodic aspiration of the gastric contents was carried out to measure gastric secretion by determining the rate of dilution of phenol red administered either separately after an overnight fast (5 ml, 280 mg/l, pH 7.4) or with the meal (40 mg/l, pH 7.4). Gastric emptying was similarly measured by the change in volume of the gastric contents. The mean intragastric volume during fasting was 8 ± 1 ml, and the fractional rate of emptying was 3.9 ± 0.6%/min or 0.31 ± 0.07 ml/min; the rate of water secretion was 0.33 ± 0.03 ml/min. The rates of ion secretion for hydrogen, sodium, potassium, and chloride were 29 ± 4, 18 ± 4, 8 ± 1, and 54 ± 9 μEq/min, resp. Instillation of a meal caused the fractional rate of emptying to increase rapidly to 17.6 ± 3.3%/min ($p<0.01$), return to the fasting level 10-40 min later, and then to increase again to 11.4 ± 2.9%/min ($p<0.02$). The rate of water secretion, following a similar time course, increased rapidly to 4.0 ± 0.6 ml/min ($p<0.001$), decreased to the fasting level 20-30 min later, and again increased significantly ($p<0.02$) 40-50 min after the meal. The hydrogen ion secretion showed a significant increase ($p<0.01$) approximately 10-30 min after the meal, as did the chloride secretion, which rose to 95-110 μEq/min. Potassium secretion increased to 12-18 μEq/min ($p<0.05$). The results demonstrate the complexity of gastric response to meal-stimulation and comprise the first study in which gastric emptying and secretion are determined simultaneously in conscious chair-adapted primates.

SECRETION AND METABOLISM

Stomach

0836 METABOLIC MEMBRANE ASPECTS OF GASTRIC H^+ TRANSPORT. (Eng.) Sachs, G.; Ghang, H.; Rabon, E.; Shackman, R.; Sarau, H. M.; Saccomani, G. (Univ. Alabama Medical Sch., University Station, Birmingham, AL 35294). *Gastroenterology* 73(4):931-940; 1977.

Information concerning the acid secretory response of the parietal cell to changes of second messengers (i.e., Ca^{2+}, cyclic AMP, or some unknown component) is reviewed. Metabolic properties of dog gastric mucosa, investigated by substrate level measurements, implicate the Krebs cycle as the major energy-yielding metabolic pathway, but are equivocal in terms of an ATP-based H$^+$ secretion. Purification of gastric membranes by centrifugation and free flow electrophoresis results in a class of membrane vesicles enriched in K$^+$-ATPase and capable of ATP-energized H$^+$ uptake. Immunohistochemistry shows these to be derived from the parietal cell. H$^+$ uptake by the vesicles is accompanied by K$^+$ efflux, and movement of either ion is not potential-coupled. The simplest interpretation of these transport studies is uptake of KCl by the vesicles by passive diffusion followed by active H$^+$:K$^+$ exchange. In some respects, however, this model fails to conform to the expectations from *in vitro* studies. It may be, therefore, that another pump (i.e., redox) or another membrane component (i.e., Cl$^-$ conductance) is lost during purification. The properties of the vesicles are such, however, as to establish their role in H$^+$ secretion by the stomach.

0837 IN VITRO RELEASE OF GASTRIN FROM ISOLATED PERFUSED ANTRUM.

(Eng.) Dretler, R.; Wesdorp, R. I.; Fischer, J. E.; Soeters, P. B.; Ebeid, A. M. (Harvard Medical Sch., Boston, MA 02114). *Am. J. Surg.* 134(2):237-241; 1977.

An isolated rat gastric antrum preparation is described that may be useful in the study of the physiology of gastrin. Gastrin antra were removed from fasting female Sprague-Dawley rats and placed in a 2-ml perfusion chamber. Reservoir bottles containing oxygenated Krebs-Ringer's A solution either as control perfusion solution or with added agent to be tested were connected to the perfusion chamber by tubes that passed through glass-jacketed heat exchange systems. Flow rate was regulated by a perfusion pump, usually at the rate of 30 ml/hr. Gastrin secretion was measured by radioimmunoassay after perfusion of the gastric antra with 50 mM acetylcholine (+ 0.1 mM eserine to prevent destruction of acetylcholine by cholinesterase), 50 mM glycine, or 30 mM or 10 mM calcium chloride added to the perfusion solution. Gastrin secretion showed a biphasic response to stimulation by acetylcholine and a single phase response to glycine and calcium chloride stimulation. Gastrin secretion from minced rather than intact antra perfused with acetylcholine showed a similar biphasic response. The biphasic release of gastrin after acetylcholine administration suggests that antral gastrin may exist in two cell populations, one of which is more accessible than the other. It is concluded that the described preparation simplifies the study of antral gastrin release, eliminating many of the inhibitory feedback mechanisms.

0838 INHIBITION OF GASTRIN RELEASE AND GASTRIC SECRETION OF ACID.

(Eng.) Stadil, F.; Rehfeld, J. F.; Christensen, K. C.; Christiansen, J.; Dano, P.; Stage, J. G. (Rigshospitalet, 2100 Copenhagen, Denmark). *Scand. J. Gastroenterol.* 11(42):25-35; 1977.

Recent studies on gastrin that are relevant to the inhibition of gastric acid secretion are summarized to provide a better understanding of the physiologic mechanisms involved. A number of physiologic systems for nervous and humoral inhibition of the secretion of gastric acid and release of gastrin are discussed. Vagal activation of the stomach, which may be cholinergic or noncholinergic, has been described in relation to the effects of epinephrine, norepinephrine, beta-adrenergic blockade, and vagotomy. The effect of diverting the gastric juice from the stomach during insulin stimulation and continuous aspiration of gastric juice are discussed. Intestinal influences, both stimulatory and inhibitory, on gastric acid secretion are presented. The intestinal actions were studied by experiments with intestinal bypass operations and on the effects of secretin, fat, and glucose administration. Intestinal inhibitors are the more important factors in gastric acid secretion and gastrin release. It is suggested that identification of these humoral inhibitors may give a better understanding of the physiologic mechanism involved.

0839 ACID HYDROLASES: ASSAY OF ACTIVITY AND LATENCY IN THE VARIED MIXED CELL POPULATIONS OF CANINE GASTRIC MUCOSA.

(Eng.) Boutros, M. I. R.; Waldron-Edward, D. (Div. Surgical Res., McGill Univ., Montreal, Quebec H3C 3G1, Canada). *Lab. Invest.* 36(4):436-443; 1977.

The specific enzymic properties, membrane or particle binding capacities, and the total activities of acid hydrolases were compared in normal canine antral and fundic mucosae and in liver. Basing each level of activity on tissue content of either protein or DNA, most of the enzymes were higher in the antrum than in the fundus, indicating that the normal, internal "digestive" or autophagic processes of the antral mucosa, with its preponderance of mucin-producing cells, are more pronounced than in the main body of the gastric mucosa. Acid phosphatase, α-galactosidase, β-galactosidase, and α-fucosidase showed differences in pH profile. In both fundic and antral tissues, acid phosphatase, although sharing the same peak of maximal activity at pH 4.8, showed a broad band of high activity in the fundic mucosa. An extra acidic peak of α-fucosidase at pH 3.3 was found in the antrum only. The specific activities of acid *p*-nitrophenylphosphatase, β-*N*-acetylglucosaminidase, α-galactosidase, arylsulfatase, α-fucosidase, and cathepsin D in the antrum (29 ± 14, 35 ± 2, 1.0 ± 0.3, 6.0 ± 0.5, 4.5 ± 0.8, and 357 ± 99 nmol/min/mg protein, resp.) were higher than those in the liver (20 ± 2, 19 ± 1, 0.39 ± 0.11, 2.7 ± 0.2, and 33 ± 2, resp., with no value given for arylsulfatase), whereas the activities of antral β-*N*-acetylgalactosaminidase, β-galactosidase, and mitochondrial succinate dehydrogenase were lower (2.1 ± 0.4 versus 2.8 ± 0.2, 2.1 ± 0.2 versus 2.9 ± 0.2, and 5.3 ± 1.6 versus 23 ± 5 nmol/min/mg, resp.). The fundic mucosa showed enzyme levels close to those of the liver with the exception of α-fucosidase, which was significantly lower than that in the liver. The high specific activity of cathepsin D in both the antrum and fundus, compared with that in the liver, suggests that the lysosomal enzymes in the canine mucosa may have a special function.

0840 CYCLIC AMP AND CYCLIC GMP IN THE RAT GASTRIC MUCOSA: THE SIGNIFICANCE OF POST MORTEM CHANGES AND TISSUE FIXATION ON THE ESTIMATION OF THE IN VIVO LEVEL. (Eng.) Ruoff, H. J. (Pharmakologisches Institut der Universitat Tubingen, Wilhelmstrasse 56, D-7400 Tubingen, W. Germany). *Naunyn Schmiedebergs Arch. Pharmacol.* 298(2):167-173; 1977.

The effects of tissue fixation and post-mortem changes on estimations of the *in vivo* levels of cyclic (c)AMP and cGMP (guanosine monophosphate) in the gastric mucosa of the rat were investigated. The tissue was fixed with microwave (MW) irradiation (2.1 kW, 2.45 megaHz), and the influence of delayed inactivation of the mucosa on the activities of adenyl cyclase (AC) and phosphodiesterase (PDE), on the levels of cAMP and cGMP, and the effects of various drugs on the levels of cAMP and cGMP were investigated in 24-hr fasted female FW49 Biberach rats. MW irradiation rapidly inactivated AC and PDE activities; 75% and 0% of AC activity remained after 5 and 25 sec, resp., and 9% and 0% of PDE activity remained after 25 and 45 sec, resp. In rats killed by decapitation, the gastric mucosal cAMP concentration doubled within 2 min after death, and the cGMP level at first (5 sec) dropped by 50% and then rose to nearly the initial concentration; 50-sec exposure of living rats to MW irradiation prevented the change in cAMP concentration, but shorter MW exposures did not. Degradation of cAMP by the MW exposure did not occur. In rats killed by decapitation and then exposed to MW for 50 sec at 5, 10, 20, 30, 60, 120, and 480 sec post-mortem, the changes in cAMP and cGMP levels were similar to those in the decapitated rats not exposed to MW, the cAMP level at 2 min, 4 min, and 8 min being significantly elevated ($p<0.001$, $p<0.001$, $p<0.005$, resp.) and the cGMP concentration at 5 sec being significantly ($p<0.01$) decreased. Hence, although MW irradiation killed the rats in 1-2 sec, longer exposures were required for mucosal fixation. Therefore, measurements made after 50-sec exposures of living rats to MWs were defined as *in vivo* levels, and measurements made in tissue fixed by 50-sec MW treatment applied 2 min after decapitation were defined as post mortem levels. Theophylline (0-200 mg/kg, i.p.) increased the *in vivo* cAMP and cGMP levels and the post-mortem cAMP level markedly and in a dose dependent manner. The post-mortem cGMP level was increased only by the highest dose ($p<0.01$), suggesting degradation of cGMP in the presence of a PDE inhibitor. Adrenalin (2 mg/kg, i.p.) increased the *in vivo* and post-mortem cAMP and cGMP levels significantly ($p<0.005$, $p<0.05$, $p<0.01$, $p<0.01$, resp.). Adrenergic β-receptor blockade with propranolol (4 mg/kg, i.p.) prevented the post-mortem rise in cAMP level ($p<0.01$), while adrenergic α-receptor blockade with phenoxybenzamine (4 mg/kg, i.p.) enhanced it ($p<0.01$), but neither drug affected cGMP levels. In adrenalectomized rats, either with or without glucocorticoid substitution, the cAMP level did not change during the post-mortem period and was significantly ($p<0.02$) lower than in sham-operated controls. These data indicate that gastric mucosal cAMP formation after delayed tissue fixation is due to β-adrenoreceptor stimulation by endogenous adrenalin, and failure to employ an adequate tissue fixation technique falsifies the estimations of *in vivo* cAMP and cGMP levels by elevating cAMP and lowering cGMP concentrations, implying that various recently published studies may not accurately describe the *in vivo* condition of the rat gastric mucosa. The results indicate that MW irradiation is an efficient method for fixation of the rat gastric mucosa.

0841 EFFECTS OF ANTRAL ETHANOL ON GASTRIC ACID SECRETION, POTENTIAL DIFFERENCE, AND SERUM GASTRIN. (Eng.) Bo-Linn, G. W.; Shanbour, L. L. (Baylor Coll. Medicine, Houston, TX). *Proc. Soc. Exp. Biol. Med.* 155(4):594-598; 1977.

The effect of antral ethanol perfusion on canine gastric acid secretion and transmucosal potential difference was studied using an *in vivo*, chambered fundic segment and isolated antral pouch preparation with intact blood supply. The preparation was responsive to exogenous gastrin with pentagastrin infusion (6 µg/kg/hr) and to endogenous gastrin with acetylcholine chloride (0.5%) and glycine (1 M) perfusion of the antral pouch. The peripheral venous serum gastrin concentration increased in response to antral perfusion with glycine with a slight increase in fundic acid secretion. A small increase in peripheral serum gastrin without a corresponding increase in acid output occurred during antral perfusion with 20% ethanol. No significant differences were found in either potential difference or acid output between saline- and ethanol-treated groups, or between histamine- and histamine-plus-ethanol-treated groups. These data suggest that ethanol-stimulated antral gastrin release is insufficient to stimulate or potentiate gastric acid secretion during acute conditions in the anesthetized dog.

0842 INTRAGASTRIC TITRATION OF ACID IN THE PERFUSED RAT STOMACH PREPARATION FOLLOWING PARENTERAL AND INTRALUMINAL STIMULATION. (Eng.) Halter, F.; Galeazzi, R.; Leuenberger, J.; Smith, G. M. (Univ. Hosp., Inselspital, Berne, Switzerland). *Eur. J. Pharmacol.* 43(3):247-252; 1977.

To develop an animal model for the clinical study of gastric acid secretion, the anesthetized rat stomach preparation was adapted to assay intraluminally administered stimulants and inhibitors of acid secretion by continuously recirculating the perfusate (15 ml of 5% glucose) and measuring acid by the pH-stat technique. The responses obtained were linear. Continuous artificial neutralization of the stomach to pH 5.5 as well as variation of the pH between 6.5 and 4.0 did not significantly alter the sensitivity of the preparation to i.v. administered human gastrin-heptadecapeptide I (HG I). Basal acid secretion, however, significantly declined following stepwise lowering of the intragastric pH between 6.5 and 4.0. The threshold values for responses to i.v. HG I were below 16 ng. Six doses could be given per rat without tachyphylaxis. Acetylcholine (1.3, 2.5, 5.2, and 10.4 μg/ml) in the perfusate induced a dose-dependent linear ($r=0.902$) acid secretion. Metiamide (1.66 mg/ml) in the perfusate produced a parallel shift to the right of the HG I dose-response curve, producing an agonist dose ratio of 3.66. These data suggest that intragastrically applied stimulants and inhibitors of acid secretion can be studied precisely in this relatively simple preparation.

0843 GASTRIC SECRETORY EFFECT OF AMINO ACIDS GIVEN ENTERALLY AND PARENTERALLY IN DOGS.

(Eng.) Landor, J. H.; Ipapo, V. S. (CMDNJ-Rutgers Medical Sch., P.O. Box 101, Piscataway, NJ 08854). *Gastroenterology* 73(4):781-784; 1977.

To investigate the possibility that the products of protein digestion, when absorbed into the bloodstream, might stimulate gastric secretion, the possible gastric secretory effect of the parenteral administration of an amino acid (AA) mixture was determined, and this effect was compared with that produced by the enteral administration of a similar AA solution. Heidenhain pouches, gastrostomies, and Roux-en-Y jejunostomies were constructed in five mongrel dogs. A 3% solution of mixed amino acids was infused at a constant rate (120 ml/hr) throughout a 2-hr period either i.v. or intrajejunally, and the secretory response of the pouches was compared to that obtained during similar infusions of 0.9% NaCl. The i.v. administration of saline did not stimulate gastric secretion. The mean secretory responses were intrajejunal saline 37 μEq/2 hr; i.v. amino acids, 330 μEq/2 hr; and intrajejunal amino acids, 301 μEq/2 hr. These results suggest that amino acids, absorbed from the gut, may play a role in the stimulation of gastric secretion occurring when food passes through the intestine.

0844 EFFECT OF REPEATED ASPIRIN ADMINISTRATION ON THE GASTRIC MUCOSAL BARRIER AND CELL TURNOVER.

(Eng.) Bolton, J. P.; Cohen, M. M. (Dept. Surgery, Univ. British Columbia, 700 West 10th Ave., Vancouver, British Columbia, V5Z IL5, Canada). *J. Surg. Res.* 23(4):251-256; 1977.

The effect of repeated aspirin administration on the canine gastric mucosa was studied by measuring gastric mucosal permeability, blood loss, and cell turnover in Heidenhain pouches. Cell turnover in the aspirin-perfused pouches (20 mM for 3 hr) was increased over that in control perfusions after a lag phase, but this did not affect the increase in gastric mucosal permeability produced by the aspirin. The increase in cell turnover may account for the observed resistance to mucosal erosions that develops after repeated aspirin administration, but the continued presence of a damaged and leaky gastric mucosal barrier may account for the failure of mucosal resistance to confer significant benefit in the form of protection from the hemorrhagic consequences of aspirin ingestion.

0845 THE EFFECT OF CIMETIDINE ON BARIUM COATING OF THE GASTRIC MUCOSA.

(Eng.) James, W. B.; Stanton, B.; Teasdale, E.; McCreath, G. (Southern General Hosp., Glasgow G51 4TF, Scotland). *Br. J. Radiol.* 50(594):445-446; 1977.

The effect of cimetidine on gastric and duodenal mucosal coating by barium sulfate was investigated in 51 men referred for barium meal examination. The patients received two placebo or cimetidine tablets (400 mg) the night before the examination and two tablets (400 mg) 1 hr prior to the examination. The quality of mucosal coating in the stomach and duodenum was graded excellent, good, or poor by three observers. Although the numbers involved were too small for statistical consideration, there was judged to be no difference between the study and control groups in the quality of mucosal coating.

0846 CIMETIDINE AND THE GASTRIC MUCOSAL BARRIER

(Eng.) Kenyon, G. S.; Ansell, I. F.; Carter, D. C. (Edinburgh Univ. Medical Sch., Edinburgh, Scotland). *Gut* 18(8):631-635; 1977.

The effect of cimetidine on hydrogen and sodium transport across the gastric mucosa and its effect on taurocholate-induced permeability changes were studied in vagally-denervated pouches of antrectomized dogs. The topical or i.v. administration of cimetidine (200 mg) did not affect the net luminal Na$^+$ gain or net luminal H$^+$ loss in the pouches. The instillation of either 5 or 20 mM sodium taurocholate caused a significant increase in Na$^+$ net gain and H$^+$ net loss. The addition of 200 mg of cimetidin to either concentration of taurocholate or its administration i.v. before taurocholate administration did not reduce the net Na$^+$ gain or H$^+$ loss induced by taurocholate alone. In the case of 5 mM taurocholate cimetidine actually increased net H$^+$ loss ($p<0.001$). As a potent inhibitor of gastric secretion, cimetidin could prove valuable by reducing the amount of secreted H$^+$ ion available to exploit a mucosal barrier damaged by agents such as bile salts.

0847 AUGMENTED GASTRIC INHIBITORY POLYPEPTIDE RESPONSE TO INTRADUODENAL GLUCOSE BY EXOGENOUS GASTRIN AND CHOLECYSTOKININ.

(Eng.) Sirinek, K. R.; Cataland, S.; O'Dorisio, T. M.; Mazzaferri, E. L.; Crockett, S. E.; Pace, W. G. (Ohio State Univ. Coll. Medicine, 410 W. 10th Ave., Columbus, OH 43210). *Surgery* 82(4):438-442; 1977.

The effect of i.v. infusions of gastrin, pentagastrin, cholecystokinin, secretin, and glucagon on both fasting and glucose-stimulated gastric inhibitory polypeptide (GIP) concentrations was studied. Five conscious dogs with Mann-Bollman fistulas each underwent six daily studies in which 50 ml of 20% glucose was infused intraduodenally (i.d.) over a period of 10 min. In five of six studies, either gastrin, pentagastrin, cholecystokinin, secretin, or glucagon was infused i.v. for 30 min before and 120 min after i.d. administered glucose. Venous blood samples at 15-min intervals were assayed for immunoreactive gastric inhibitory peptide (GIP). The i.v. administration of gastrin, pentagastrin, cholecystokinin, secretin, and glucagon had no effect on fasting immunoreactive GIP (iGIP). Compared to fasting, iGIP was significantly ($p<0.05$) increased at 15, 30, and 45 min for all treatment groups. Compared to i.d. administered glucose alone, the GIP response following either i.v. gastrin plus i.d. glucose, i.v. pentagastrin plus i.d. glucose, or i.v. cholecystokinin plus i.d. glucose was significantly greater ($p<0.05$) at 5 and 15 min. This study demonstrates augmentation of glucose-stimulated GIP by the structurally similar peptides, gastrin, pentagastrin, and cholecystokinin, suggesting a physiological role for endogenous gastrin and cholecystokinin in modulating the GIP response to glucose.

0848 ACID SECRETORY RESPONSES TO HISTAMINE, PENTAGASTRIN, AND FEEDING BEFORE AND AFTER VAGAL DENERVATION OF FUNDIC POUCHES IN CATS.

(Eng.) Svensson, S. O.; Emas, S. (Karolinska Hosp., 104 01 Stockholm, Sweden). *Scand. J. Gastroenterol.* 12(3): 357-362; 1977.

The effect of local vagotomy of the fundic pouch on the acid secretory response to histamine, pentagastrin, and feeding was studied in cats. A gastric fistula (GF) of the innervated stomach, and a vagally innervated mucosal septal fundic pouch (Pavlov pouch, PP) were prepared in each of five adult cats at least 1 month prior to the experiments. Each experiment was repeated after converting the PP to a Heidenhain pouch (HP). Saline was infused i.v. (12.5 ml/hr) and histamine (10-640 µg/kg/hr) or pentagastrin (0.5-64 µg/kg/hr) was added to the infusion for 3 hr. Feeding experiments used a single meal of 3-50 g ground meat and were conducted without saline. Before denervation, the maximal response (MR) of the GF to histamine and pentagastrin was 1.04 ± 0.08 and 0.96 ± 0.05 mEq of acid/15 min, resp., and the dose-response (DR) curves levelled off at 160 and 8 µg/kg/hr for histamine and pentagastrin, resp. The D_{50} was 42 ± 9 and 2.6 ± 0.8 µg/kg/hr for histamine and pentagastrin, resp. Denervation did not affect these secretory parameters for histamine in the GF, but did elevate the MR ($p<0.01$) and lower the D_{50} ($p<0.01$) for pentagastrin. In the PP, the MR to histamine, pentagastrin, and feeding were approximately equal (0.36, 0.33, and 0.31 mEq/15 min, resp.); the DR curve plateaued at 160 and 32 µg/kg/hr of histamine and pentagastrin, resp., and at 12.5 g of meat. The D_{50} for histamine and pentagastrin was 29 ± 4 and 2.0 ± 0.7 µg/kg/hr, resp. Denervation to produce the HP markedly reduced the MR to histamine, pentagastrin, and feeding (0.20, 0.21, and 0.13 mEq/15 min, resp.); the DR curve plateau became variable for both histamine and pentagastrin and was markedly depressed for feeding; the D_{50} for histamine did not change (45 ± 6 µg/kg/hr), and was significantly ($p<0.05$) for pentagastrin. Denervation reduced the acid response to histamine by decreasing the secretory capacity, and to pentagastrin by decreasing both the secretory capacity and the sensitivity of the oxyntic glands (in this respect, the effect of local and truncal vagotomy is equal in cats). The reduction of the response to feeding was greater than to histamine or pentagastrin, which indicates that feeding does not release enough gastrin to induce the maximal rate of acid secretion in the absence of vagal impulses. But, because feeding and pentagastrin produced equal MR before denervation, it appears that vagal impulses during feeding produce greater enhancement than does basal vagal tone of the acid response to submaximal doses of gastrin.

0849 CHANGES IN PROTEIN AND NUCLEIC ACID SYNTHESIS IN RAT GASTRIC MUCOSA AFTER PENTAGASTRIN.

(Eng.) Enochs, M. R.; Johnson, L. R. (Dept. Physiology, Univ. Texas Medical Sch., Houston, TX 77030). *Am. J. Physiol.* 232(2):E223-E228; 1977.

Pentagastrin was administered to rats to determine the effect of a single dose of the substance on protein and nucleic acid syntheses in the gastric mucosa. Fasted rats received i.p. either 250 µg/kg of pentagastrin or an equal volume of saline at intervals from 0 to 24 hr prior to sacrifice. Tissue from the oxyntic gland area and the duodenum were then minced and incubated in a ^{14}C-amino acid mixture (2 µCi/ml) to measure *in vitro* amino acid incorporation. Amino acid incorporation into stomach tissue and duodenal protein was significantly elevated ($p<0.05$ and 0.025, resp.) by 6 hr, and the secreted protein was significantly less ($p<0.01$) than in controls. The inhibitory effect of actinomycin D on protein synthesis was tested by comparing the incorporation of ^{14}C-amino acids into oxyntic glandular mucosa in rats that had received i.p. injections of either actinomycin D (100 µg at 24 and 7 hr before sacrifice), pentagastrin (250 µg/kg at 6 hr before sacrifice), actinomycin D and pentagastrin (schedules as given for solo doses), or saline. Pentagastrin significantly ($p<0.005$) increased incorporation of label into total gastric mucosal protein; pentagastrin plus actinomycin D significantly decreased protein synthesis compared to controls ($p<0.001$); actinomycin D alone had no significant effect. The influence of pentagastrin on nucleic acid synthesis was measured by injecting rats with either 250 µg/kg of pentagastrin or with saline at various times before sacrifice; all animals received 200 µCi ^{3}H-orotic acid i.p. 2 hr prior to sacrifice. At 1 and 2 hr after its injection, pentagastrin significantly increased incorporation of ^{3}H-orotic acid into messenger RNA (from 0.45 and 0.39 to 0.72 and 0.55 disintegrations per min [dpm]/mg DNA, resp.). Pentagastrin also induced a biphasic increase in ribosomal RNA and transfer RNA that reached a maximum of 4.59 dpm/mg by 12 hr (control=2.82 dpm/mg). The results indicate that the main trophic effect of pentagastrin on rat gastric mucosa was an increase in protein synthesis, dependent on and preceded by increased RNA synthesis.

0850 INHIBITION OF GLUCOSAMINE SYNTHESIS BY SALICYLATES, HYDROCORTISONE AND TWO NON-ULCEROGENIC DRUGS.

(Eng.) Goodman, M. J.; Kent, P. W.; Truelove, S. C. (Dept. Medicine, Univ. Chicago, Chicago, IL). *Arch. Int. Pharmacodyn.* 226(1):4-10; 1977.

Glucosamine synthesis in homogenates of human gastric and colonic mucosa was studied in the presence of the ulcerogenic drugs sodium salicylate, acetylsalicylic acid, and hydrocortisone hemisuccinate, and in the presence of the nonulcerogenic analgesic, paracetamol. The nonulcerogenic antibiotic, gentamicin, was tested for its effect upon glucosamine synthesis in a homogenate of human colonic mucosa. The homogenates (50 mg tissue/ml) were incubated in 1.0 ml volumes of substrate buffer mixture containing 1, 2, 5, or 10 mg of a drug (only 1, 2, or 5 mg for acetylsalicylic acid) 37 C for 3 hr. Concentrated perchloric acid (71%) was used to stop the reaction. After centrifugation, glucosamine was assayed by the Morgan-Elson color reaction. Dose-related inhibition of glucosamine synthesis was observed with each drug. Sodium salicylate, acetylsalicylic acid, and paracetamol produced 50% inhibition at concentrations of 27, 23, and 29 mM, resp., while hydrocortisone hemisuccinate produced 50% inhibition at 10 mM. Gentamicin inhibited glucosamine synthesis to approximately the same extent as the salicylates. The results indicate that the ulcerogenic actions of the salicylates and hydrocortisone hemisuccinate are not due to the inhibition of glucosamine synthesis in the mucosa.

0851 INHIBITION BY SOMATOSTATIN OF GASTRIN RELEASE AND GASTRIC ACID RESPONSES TO MEALS AND TO PENTAGASTRIN IN MAN.

(Eng.) Phillip, J.; Domschke, S.; Domschke, W.; Urbach, H. J.; Reiss, M.; Demling, L. (Dept. Medicine, Univ. Erlangen-Nurnberg, Erlangen, W. Germany). *Scand. J. Gastroenterol.* 12(3):261-265; 1977.

Somatostatin was administered i.v. to six healthy male volunteers to investigate its effect on meal- and pentagastrin-induced acid secretion and gastrin release. Somatostatin (5 µg/kg/hr, cyclic form) was administered during the second hour of a 3-hr period of stimulation with either pentagastrin (1.5 µg/kg/hr, i.v.) or a test meal (10% peptone, pH 5.5). A modified Fordtran and Walsh method of intragastric titration was used to determine meal-induced gastric acid secretion. Somatostatin decreased the pentagastrin-induced acid response achieved by the first hour of stimulation by 68 ± 17% ($p<0.001$) and by 87 ± 2% ($p<0.001$) during the last 30 min of somatostatin infusion. The total 1-hr pepsin output was decreased by 72 ± 14% ($p<0.001$) and by 84 ± 2% ($p<0.001$) during the last 30 min. The total 1-hr meal-induced acid secretion was reduced by 75 ± 21% ($p<0.001$) by somatostatin (by 96 ± 3% [$p<0.001$] during the last 30 min of infusion). Meal-stimulated gastrin levels, nearly twice the fasting levels, were decreased only 27 ± 9% ($p<0.02$) even during the second 30 min of infusion. The results suggest that somatostatin inhibits meal-induced acid secretion mainly by a direct effect on the parietal cells and only partially by indirect inhibition via suppression of gastrin release.

0852 EFFECT OF SOMATOSTATIN ON GASTROINTESTINAL SECRETIONS AND PEPTIC ULCER PRODUCTION IN CATS.

(Eng.) Konturek, S. J.; Radecki, T.; Pucher, A.; Coy, D. H.; Schally, A. V. (Inst. Physiology, Medical Acad., Krakow, Poland). *Scand. J. Gastroenterol.* 12(3):379-383; 1977.

Somatostatin (GH-RIH) was infused i.v. into conscious cats to study its effect on gastric and pancreatic secretion and the formation of peptic ulcers. Chronic gastric and pancreatic fistulas were prepared in six cats, and a gastric (pentagastrin or histamine, i.v.) or pancreatic (secretin, i.v. or intraduodenal acid) stimulant was administered to produce maximal secretion. After 90 min of secretory stimulation, GH-RIH (0.62-5.0 µg/kg/hr) was infused i.v. for 1 hr, followed by an additional 60-min administration of the stimulant. Peptic ulcer formation was studied in 48 cats after a 36-hr perfusion with one of the following solutions: histamine (160 µg/kg/hr) or pentagastrin (8 µg/kg/hr) alone or with GH-RIH (2 µg/kg/hr). GH-RIH produced a dose-related inhibition of pentagastrin-stimulated acid secretion, reaching approximately 50% inhibition at a dose of 2 µg/kg/hr. Pepsin inhibition was about 90% at 1 µg/kg/hr of GH-RIH, but was not dose-related. GH-RIH had no effect on histamine-stimulated acid output, but did significantly decrease pepsin output. GH-RIH (2 µg/kg/hr) almost completely inhibited secretin-stimulated pancreatic bicarbonate secretion, and strongly inhibited bicarbonate secretion stimulated by intraduodenal acid, but did not affect protein secretion induced by either stimulant. GH-RIH significantly reduced the incidence and size of duodenal ulcers induced by pentagastrin. Peptic ulcers and related complications were also decreased by GH-RIH. It is concluded that GH-RIH may directly affect the oxyntic glands, but not the histamine receptors. Furthermore, GH-RIH may be useful in treatment of peptic ulcers in man.

0853 EFFECT OF SOMATOSTATIN ANALOGS ON GASTRIC AND PANCREATIC SECRETION.

(Eng.) Konturek, S. J.; Tasler, J.; Krol, R.; Dembinski, A.; Coy, D. H.; Schally, A. V. (Medical Acad., Krakow, Poland). *Proc. Soc. Exp. Biol. Med.* 155(4):519-522; 1977.

Somatostatin and its two analogs, D-^{8}Trp-somatostatin and D-^{14}Cys-somatostatin were tested for their effects on gastric and pancreatic secretion in chronic gastric and pancreatic fistula dogs. All three peptides, infused i.v. at 2.5 µg/kg/hr, caused similar competitive inhibition of pentagastrin-induced gastric acid and secretin-induced pancreatic bicarbonate secretions. During somatostatin infusion, the dose-response curve for acid secretion from the stomach was shifted to the right; there was an almost threefold increase in K_m, while V_{max} was only slightly decreased. The infusion of either analog produced a similar shift of the dose-response curve, a doubling of K_m, and a small reduction in V_{max}. Somatostatin and its analogs all shifted the dose-response curve for pancreatic bicarbonate secretion to the right, increased the K_m, and slightly reduced V_{max}. The results indicate that somatostatin analogs, which were shown to have a dissociated action on pituitary and endocrine pancreatic secretion, are essentially as equipotent as somatostatin itself on gastric and pancreatic secretions.

0854 ANTI-STRESS ULCER AND ANTI-SECRETORY EFFECT OF SOMATOSTATIN IN RATS--FAILURE TO SUPPRESS SERUM GASTRIN. (Eng.) Schwille, P. O.; Putz, F.; Thun, R.; Schellerer, W.; Draxler, G.; Lang, G. (Chirurgische Universitatsklinik, Maximiliansplatz D-8520 Erlangen, W. Germany). *Acta Hepatogastroenterol.* 24(4):259-265; 1977.

The effect of somatostatin on stress ulceration and on gastrin secretion was investigated in rats. Some rats were restrained so that free movement was restricted, while others were completely restrained. Complete restraint reduced the volume of gastric secretion, acid and pepsin secretion, the acid concentration, and aminopyrine clearance, while the ulcer index was elevated. During both types of restraint, somatostatin inhibited the volume and acid secretion in a dose-dependent manner and lowered the ulcer index. During continuous somatostatin infusion (10.0 μg/kg/hr, 8 hr), the acid concentration and acid and pepsin secretion fell. The ulcer index of gastric fistula in somatostatin-treated rats dropped to 50% of that in vehicle-treated controls. Microcirculation and serum gastrin levels were unchanged. In animals without gastric fistula, the ulcer index was reduced by 85%; the serum gastrin level was unchanged. It is concluded that stress ulcers develop at a low secretory and microcirculatory state of gastric mucosa. The prophylactic effect of somatostatin results from direct inhibition of parietal and chief cells.

Pancreas

0878 PURIFICATION OF PLASMA MEMBRANES FROM RAT PANCREAS: A RAPID METHOD. (Eng.) Poirier, G. G.; Lambert, M. P.; Lebel, D.; Sakr, F.; Morisset, J.; Beaudoin, A. R. (Faculty of Sciences, Univ. Sherbrooke, Quebec J1K 2R1, Canada). *Proc. Soc. Exp. Biol. Med.* 155(3):324-329; 1977.

A rapid and simple method for the isolation of plasma membranes from the rat pancreas is described. Pancreases are homogenized in buffer A. The homogenate is filtered through cheesecloth and centrifuged at 50 x *g* for 5 min to remove RBC, unbroken cells, and connective tissue. The supernatant is then centrifuged at 5,100 x *g* for 20 min. The top layer of the 5,100 x *g* pellet is removed for further purification on a sucrose gradient. The separated layer is mixed with 75% sucrose to a final concentration of 40% and inserted in a stepwise sucrose gradient of 25, 30, 35, and 40% (containing the 5,100 x g pellet). This gradient is centrifuged for 1 hr at 115,000 x g. The different fractions are removed with a syringe and diluted with buffer B containing 40 mM Tris-HCl, pH 7.4, 0.25 M sucrose, 1 mg/ml albumin, and 5 mM β-mercaptoethanol. They are then centrifuged at 30,000 x g. Electron microscopy of the material recovered at the interface of sucrose 30-35% showed that it consisted mainly of smooth vesicular membranes, although some contamination by rough endoplasmic reticulum was observed. The specific activity of adenylate cyclase in the material sedimenting at the interface 30-35% and identified as smooth vesicular membranes by electron microscopy demonstrated a 44-fold increase in activity in comparison with that in the homogenate. The succinate dehydrogenase activity, a mitochondrial marker, was low in the adenylate-cyclase-rich fraction, and α-amylase was practically absent from the purified fraction. There was a sevenfold decrease in RNA content as compared to the total homogenate, which could be explained by the small contamination by rough endoplasmic reticulum. The optimal concentration of secretin necessary to obtain maximal stimulation of adenylate cyclase activity was 2 clinical U/ml. This method has several improvements over other techniques: the new finding that succinate dehydrogenase activity is decreased and the use of the RNA content as a marker for rough endoplasmic reticulum contamination. This method also provides an excellent tool for the study of the interaction of secretin and other hormones with the membrane.

0879 EXOCRINE PANCREAS RESPONSE TO A TEST MEAL IN THE DOG: CHANGES INDUCED BY 3 MONTHS' ETHANOL FEEDING.

(Eng.) Tiscornia, O. M.; Singer, M.; Mendes De Oliveira, J. P.; Demol, P.; Sarles, H. (Unite de Recherches de Pathologie Digestive, INSERM U31, 46 chemin de la Gaye, 13009 Marseilles, France). *Am. J. Dig. Dis.* 22(9):769-774; 1977.

Pancreatic secretion in response to a test meal was compared in nonalcoholic dogs and in those fed ethanol for 3 months. Three dogs were equipped with a chronic gastric fistula (Thomas cannula) and a new type of chronic pancreatic fistula that allows collection of pure nonactivated pancreatic juice after ingestion of a test meal. During the nonalcoholic period, a test meal (400 g canned dog meal) was given simultaneous with an infusion of 200 ml isotonic saline through the gastric cannula. Volume, bicarbonate concentration and output, and protein output showed a peak 40 min after ingestion of the test meal. Protein concentration showed an opposite pattern. During the alcoholic period, the animals were given 50% ethanol (2.0 g/kg/day) associated with a protein-supplemented diet through the gastric cannula, and test meal experiments were repeated at the end of this period. When compared with the nonalcoholic period, the secretory response to the meal was significantly modified; volume (-42%) and bicarbonate concentration (-19%) and output (-54%) were significantly lower, protein output remained unchanged, and protein concentration increased (+74%). All three dogs excreted protein plugs through the catheter collecting pancreatic juice from the main pancreatic duct. It is postulated that a depression of secretin release and an increased gastrin release and cholinergic tone could be the basis of the ethanol-evoked change in response to a test meal.

0880 CANINE PANCREATIC EXOCRINE SECRETORY RESPONSE TO LOW- AND HIGH-FAT ELEMENTAL DIETS.

(Eng.) Lewis, J. W.; Freeman, J. B. (Univ. Iowa Hosp. and Clinics, Iowa City, IA 52242). *Can. J. Surg.* 20(4):345-348; 1977.

The response of the dog exocrine pancreas to intragastric infusions of a commercially available diet with 30% of the calories present as fat (Flexical) was compared to that of a similar diet that was essentially fat-free (Vivonex). Each of these diets, as well as a standard tube feeding formula, was infused at the rate of 2 ml/min for 2 hr on each of 3 days. The volume and protein and bicarbonate content of eight 15-min samples of pancreatic secretion collected via a pancreatic pouch in the 2-hr period were measured. The high-fat elemental diet produced significantly ($p<0.05$) greater volume and bicarbonate output than did the low-fat elemental diet or the standard formula. Protein content of the pancreatic secretion was significantly ($p<0.01$) reduced during infusions of either low- or high-fat elemental diets compared to the standard diet, indicating decreased enzyme output. It is concluded that low-fat elemental diets are preferable for enteral nutrition in patients with pancreatic disorders where limitation of pancreatic secretions is desirable.

0881 CALCITONIN AND EXOCRINE PANCREATIC SECRETION IN MAN: INHIBITION OF ENZYMES STIMULATED BY CCK-PANCREOZYMIN, CAERULEIN, OR CALCIUM--NO RESPONSE TO VAGAL STIMULATION.

(Eng.) Hotz, J.; Goebell, H.; Ziegler, R. (Medical Clinic, Univ. Essen, Hufelandstr. 55, D4300 Essen 1, W. Germany). *Gut* 18(8):615-622; 1977.

The effect of calcitonin on human pancreatic secretion was studied under various conditions of stimulation. During a continuous i.v. infusion of both secretin plus cholecystokinin-pancreozymin (CCK-PZ, 1 U/kg/hr for each hormone) or secretin plus cerulein (1 U/kg/hr secretin, 75 μg/kg/hr cerulein), enzyme secretion was promptly reduced by an infusion of calcitonin (60 Medical Research Council U/hr) by more than 50%. In contrast, vagally stimulated enzyme secretion induced by insulin-hypoglycemia or carbamyl-choline was not altered against a background infusion of calcitonin in comparison with control experiments. Calcium-induced enzyme secretion was abolished by additional calcitonin infusion, which also prevented an increase in serum calcium. An additional high grade calcium infusion did not modify the inhibitory action of calcitonin on enzyme output stimulated by secretin and CCK-PZ. Fluid and bicarbonate secretion remained unaffected by calcitonin in all experimental conditions, whereas the outputs of calcium and magnesium paralleled generally the changes in enzymes. It is suggested that calcitonin interferes with hormone-mediated stimulation of the acinar cells without influencing cholinergic mechanisms. The inhibitory action of calcitonin on enzyme secretion does not appear to be mediated by a depletion of extracellular calcium in the pancreatic tissue by calcitonin.

0882 IN VITRO EFFECTS OF SECRETIN AND VASOACTIVE INTESTINAL POLYPEPTIDE ON HYDROLASE SECRETION AND CYCLIC AMP LEVELS IN THE PANCREAS OF FIVE ANIMAL SPECIES. A COMPARISON WITH CERULEIN. (Eng.) Robberecht, P.; Deschodt-Lanckman, M.; Lammens, M.; De Neef, P.; Christophe, J. (Faculte de Medecine, Universite libre de Bruxelles, bvd de Waterloo 115, B-1000 Brussels, Belgium). *Gastroenterol. Clin. Biol.* 1(6/7):519-525; 1977.

The *in vitro* effects of secretin, vasoactive intestinal polypeptide (VIP), and cerulein on hydrolase (amylase and lipase) secretion in pancreas fragments from the rat, mouse, guinea pig, cat, and dog were studied. Cyclic AMP levels were also measured to determine a correlation with hydrolase secretion. Cerulein stimulated pancreatic hydrolase secretion in all five species. Secretin and VIP were potent stimuli of enzyme secretion in the rat and guinea pig only. A greater amylase response to VIP than to secretin was observed in the rat, whereas the opposite was true in the guinea pig. The peptide concentration required for maximal stimulation was 100-fold higher for secretin or VIP than for cerulein. Cyclic AMP levels increased in pancreas fragments from all five species exposed to secretin or VIP, but cerulein had no effect on the intracellular levels of cyclic AMP. No quantitative correlation between cyclic AMP increase and amylase secretion in response to VIP and secretin was observed in the rat; in the guinea pig, VIP was a better stimulus than secretin of hydrolase secretion, and the reverse was true for the cyclic AMP response. These data confirm that in the rat and guinea pig pancreatic hydrolase secretion is stimulated *in vitro* by two different mechanisms, one involving cyclic AMP and the other involving cyclic guanosine 3',5' monophosphate and calcium.

0883 BIOCHEMICAL REACTIONS INVOLVED IN PANCREATIC ENZYME SECRETION. 2. INHIBITORY EFFECTS OF TETRACAINE AND ATROPINE. (Eng.) Morisset, J.; Beaudoin, A. R. (Dept. Biology, Univ. Sherbrooke, Sherbrooke, Quebec J1K 2R1, Canada). *Can J. Physiol. Pharmacol.* 55(3):639-643; 1977.

The inhibitory effects of tetracaine on cholecystokinin-pancreozymin (CCK-PZ)- and urecholine-stimulated pancreatic enzyme secretion and the potentiating effect of these drugs on dibutyryl cyclic AMP-stimulated enzyme secretion were investigated in male Sprague-Dawley rats; the effect of tetracaine on calcium efflux was also studied. Tetracaine pretreatment (2 mM, 30 min) did not modify basal amylase release, but the secretory response to urecholine (10^{-5} M) was subsequently reduced by 70%. The response to CCK-PZ (2 Ivy U) was not affected. When tetracaine was added to medium already containing both CCK-PZ and urecholine (10 min after the start of incubation), amylase release was not significantly affected. Co-addition of atropine (10^{-5} M) and urecholine to pancreatic tissue for 30 min resulted in complete inhibition of amylase secretion. The addition of atropine to tissue already stimulated by the cholinergic drug was associated with a 48% decrease in amylase secretion. The secretory response to CCK-PZ was not modified by atropine. Both CCK-PZ and tetracaine increased calcium efflux over the control level when added separately; when combined, a further increase in calcium release was observed. Urecholine caused a rapid release of calcium within the first 15 min, but addition of tetracaine to the cholinergic was not associated with a further increase in calcium efflux. When dibutyryl cyclic AMP was substituted for CCK-PZ and urecholine, there was a significant increase in calcium efflux that was less pronounced than that after CCK-PZ or urecholine. The effect of tetracaine on calcium efflux might partly explain the inhibitory action of the drug.

0884 EXOCRINE PANCREATIC INSUFFICIENCY SYNDROME IN CBA/J MICE. III. PATHOLOGICAL AND GENETIC ANALYSIS. (Eng.) Leiter, E. H.; Cunliffe-Beamer, T. (Jackson Lab., Bar Harbor, ME). *Gastroenterology* 73(2):260-266; 1977.

The clinical and histopathological characteristics of exocrine pancreatic insufficiency (EPI) syndrome were studied in CBA/J mice fed diets of protein and fat *ad libitum*. Exocrine pancreatic function was measured by a gelatin digestion test for fecal proteolytic activity. Two groups of 7- to 11-week-old female EPI mice were given protein/fat diets supplemented with either 0.5 or 1.0 g of pancreatin/30.0 g diet for 14 weeks; and weight changes during the next 17 weeks were compared with those in control mice. Plasma glucose and insulin levels were measured in EPI and normal mice and genetic analysis of the EPI syndrome was also performed. The sera of EPI mice were tested for antibody to Coxsackie viruses B1 and B6; the sera of normal CBA/J mice were tested for antibody to reovirus III; and sonicated pancreatic extracts were examined for type C group-specific viral antigen p30 by complement fixation testing. Gross and histopathological characteristics of EPI mice were emaciation, distention of the bowels, and replacement of exocrine pancreatic tissues by fat. Subclinical signs of the disease were focal areas of degeneration and inflammatory cell infiltration in the exocrine pancreas. EPI mice not treated with pancreatin had no fecal tryptic activity, but subclinical stages of the disease could not be detected by this test. Pancreatin produced significant, but reversible, increases in general health and body weight in EPI mice. EPI mice receiving long-term pancreatin treatment were normoglycemic (121 mg plasma glucose/100 ml), while untreated EPI mice were hypoglycemic (81 mg/100 ml). Both treated and untreated mice showed normal plasma insulin levels (40-60 μU/ml), indicating that EPI syndrome did not affect islet function. Matings of normal parents, normal parents with at least one previous EPI offspring, and EPI parents produced EPI progeny at frequencies of 1.4, 2.6, and 3.8%, resp., suggesting that the disease occurs spontaneously. Preweaning mortality in mice from EPI breeders was not due to early expression of a recessive gene as the incidence of mortality (37.8%) was markedly decreased to 3.2% by fostering 1-day-old neonates to asymptomatic CBA/J females. The trait could not be outcrossed to other strains, and no evidence of viral etiology was observed. The results indicate that the cause of exocrine cell necrosis characteristic of EPI is not genetic, but that there is a genetically predisposing background in EPI in the CBA/J strain.

0885 ACUTE PANCREATITIS FOLLOWING INTRAPANCREATIC COMPLEMENT ACTIVATION IN THE RAT. (Ger.) Seelig, R.; Seelig, H. P.; Rohnacher, R. (Institut fur Immunologie und Serologie, Universitat Heidelberg, D-6900 Heidelberg, W. Germany). *Z. Gastroenterol.* 14(6):654-667; 1976.

Adult Sprague-Dawley rats were sensitized with rabbit IgG (9 mg/week for 4 consecutive weeks, s.c.), and intrapancreatic Arthus phenomenon was induced in the animals with an antibody titer of 1/8 by the intraductal injection of rabbit IgG (4 mg) 7 days after the last sensitization. The intrapancreatic immune complex reaction caused acute pancreatitis (acinus cell necrosis, intravasal leukocytosis, leukodiapedesis, leukocyte infiltration of the walls of veins and capillaries, and, ultimately, interstitial leukocyte infiltration). Rabbit IgG administered to nonsensitized rats and bovine albumin administered intraductally to sensitized rats failed to induce acute pancreatitis. Complement reactivation with acute pancreatitis similar to that seen after the intraductal administration of rabbit IgG was induced in sensitized rats by the intraductal administration of inulin (15 and 30 mg) and cobra venom factor (45 or 200 U). The localization of the early acinus cell necrosis and of the maximal leukocyte infiltration was determined basically by the site of the primary complement activation. The extent of the necrosis was dependent on the diffusion of the complement-activating substance in the interstitial edema. Following the intraductal injection of inulin and cobra venum factor, the activation of the complement system was triggered via the C3 shunt, leading the release of cytolytically active complement and biologically active mediators from the complement system, independent of immune reactions. The findings indicate that intrahepatic complement activation by immunological and nonimmunological processes leads to acute necrotizing pancreatitis, with the release of cytolytically active complement being the common pathogenetic occurrence in the initial acinus cell membrane lesion.

SECRETION AND METABOLISM

Hepatobiliary Tract

0892 ADRENERGIC MECHANISMS IN THE HEPATIC MICROCIRCULATION IN THE RAT. (Eng.) Koo, A.; Liang, I. Y. S.; Cheng, K. K. (Dept. Physiology, Univ. Hong Kong, Sassoon Rd., Hong Kong). *Q. J.*

Exp. Physiol. 62(3):199-208; 1977.

To elucidate the role of adrenergic constrictor-dilator mechanisms in the hepatic sinusoids in the control of blood flow in the terminal hepatic microcirculation, the *in vivo* rat liver microvascular bed was examined microscopically, and the diameter of the hepatic sinusoids was measured by serial photomicrography. The intraportal infusion of epinephrine, norepinephrine, and tyramine produced a constriction of the sinusoids at all concentrations (10^{-9}-10^{-4} M), but dilatation of some sinusoids occurred when the concentrations were low (10^{-9}-10^{-7} M). The effects of tyramine on the sinusoids were attributed to the release of endogenous norepinephrine, which activated either alpha- or beta-adrenergic receptors, causing either constriction or dilatation, resp. Alpha-adrenergic blockade with phenoxybenzamine (1 mg/kg) caused a significant increase in the mean diameter of the sinusoids (6.3 ± 0.05 versus 6.5 ± 0.05 µm, $p<0.001$) after 30 min. Beta-adrenergic blockade by propranolol (1 mg/kg) induced a significant constriction of the sinusoids. All the above responses were abolished by pretreatment with reserpine. The automatic control of sinusoidal blood flow may be regulated by norepinephrine-mediated basal vasomotor tone in the hepatic sinusoids.

0893 HEPATIC SUPPORT WITH HEPATOCYTE SUSPENSIONS IN A PERMEABLE MEMBRANE DIALYZER.

(Eng.) Olumide, F.; Eliashiv, A.; Kralios, N.; Norton, L.; Eiseman, B. (Denver General Hosp., Denver, CO 80220). *Surgery* 82(5):599-606; 1977.

A new concept of hepatic support with circulating hepatocytes on one side of a cuprophan membrane and blood from an anhepatic pig on the other was evaluated in 19 dialysis experiments. Levels of pyruvate metabolism (50% of an initial value of 480 counts/min in $^{14}CO_2$ produced from 2-^{14}C-pyruvate/10^6 cells after 2-4 hr of perfusion) and oxygen utilization (0.01 ml O_2/g liver/min after 4 hr of perfusion) were similar to those obtained in previous experiments, when liver cells in a centrifuge are perfused with oxygenated plasma. Of six anhepatic pigs given late hepatic support, five showed neurologic improvement. One had concomitant improvement in electroencephalographic results. A membrane hemodialysis unit in which hepatocytes circulate against blood from an anhepatic animal is the most suitable extracorporeal liver support unit described so far. Its simplicity allows repeated and prolonged use.

0894 CHANGES IN THE BLOOD-BRAIN BARRIER IN HEPATIC COMA AFTER HEPATECTOMY IN THE RAT.

(Eng.) Livingstone, A. S.; Potvin, M.; Goresky, C. A.; Finlayson, M. H.; Hinchey, E. J. (Montreal General Hosp., 1650 Cedar Ave., Montreal, Quebec H3G 1A4, Canada). *Gastroenterology* 73(4): 697-704; 1977.

The possibility that the hepatic coma seen after massive liver necrosis or hepatectomy may result from an alteration in the blood-brain barrier was examined. Bloodless two-stage hepatectomies were performed on Wistar rats, and the animals were maintained with i.v. glucose infusions. When the animals were in late stage 3 or stage 4 hepatic coma, the functional integrity of the blood-brain barrier was assessed by means of the sudden arterial injection-15-sec decapitation-Oldendorf tissue residue technique, and by the i.v. injection of trypan blue. The former showed that the barrier had become permeable to D-sucrose, inulin, and L-glucose, substances that usually do not cross the barrier; the latter showed that the barrier had also become permeable to trypan blue, so that the brains of the comatose animals stained blue whereas normal brains did not. The brains of comatose animals uniformly showed cerebral edema on gross examination (their water contents were increased), and, on electron microscopic examination, their astrocytes were swollen, especially in pericapillary locations. The break in the barrier appears to be associated with the formation of cerebral edema, and implies both that substances that usually do not gain access to the brain parenchyma can now do so and that substances usually conserved, such as neurotransmitters, can now escape.

0895 CAN HEPATIC COMA BE CAUSED BY A REDUCTION OF BRAIN NORADRENALINE OR DOPAMINE?

(Eng.) Zieve, L.; Olsen, R. L. (Veterans Admin. Hosp., Minneapolis, MN 55417). *Gut* 18(9):688-691; 1977.

The hypothesis that reduction in brain dopamine or norepinephrine causes hepatic coma was tested in male Sprague-Dawley rats. Intraventricular infusions of octopamine (3.2 mg over 290 min), which raised brain octopamine concentrations more than 20,000-fold, resulted in reduction in brain norepinephrine and dopamine by as much as 90% without affecting the alertness of activity of normal rats. As this reduction of brain catecholamines is much greater than any reported in hepatic coma, the values observed in experimental hepatic failure probably have no etiological significance for the encephalopathy that ensues.

0896 THE EFFECT OF GLUCAGON AND BLOOD TRANSFUSION ON HEPATIC CIRCULATION AND OXYGEN CONSUMPTION IN HEMORRHAGIC SHOCK.

(Eng.) Lindberg, B.; Darle, N. (Sahlgrenska sjukhuset, S-413 45 Goteborg, Sweden). *J. Surg. Res.* 23(4):257-263; 1977.

Experiments were carried out to determine whether the injection of glucagon combined with blood transfusions could increase liver blood flow and oxygen consumption in the treatment of hemorrhagic shock. Ten pigs were subjected to a standard shock model, including two 30-min periods of hemorrhagic shock at 50 mm Hg. After the first period of shock, glucagon (50 µg/kg) was administered i.v., and the shed blood was transfused. Portal vein and hepatic artery flow as well as oxygen consumption were measured. Both periods of shock resulted in a marked decrease in blood flow as well as oxygen consumption. Treatment with glucagon and blood transfusion resulted in an increase in hepatic artery flow to 300% of the preshock value, but no significant increase in the portal vein flow occurred compared with blood transfusion alone. The high hepatic artery flow caused a very high inflow of oxygen to the liver. In spite of this high inflow of oxygen, the liver oxygen consumption was not significantly higher than after blood transfusion alone. Glucagon administration to pigs in hemorrhagic shock does not increase portal vein flow, as it does in dogs.

0897 THE EFFECT OF DEXTRAN 40 AND BLOOD TRANSFUSION ON HEPATIC CIRCULATION AND OXYGEN CONSUMPTION IN HEMORRHAGIC SHOCK.

(Eng.) Lindberg, B.; Darle, N. (Sahlgrenska sjukhuset, S-413 45 Goteborg, Sweden). *J. Surg. Res.* 23(4):264-273; 1977.

The effect of treatment with dextran 40 and blood transfusion on hepatic circulation and oxygen consumption was studied in pigs subjected to a standard model of hemorrhagic shock. The animals were bled to 50 mm Hg arterial pressure and kept at this pressure for 30 min, one group being treated with the shed blood and the other group with an equal volume of dextran 40. Thirty minutes after completion of the treatment, the animals were once again bled to 50 mm Hg and kept at this level for 30 min. During the first period of shock the flow in both vessels decreased to 53% of the baseline value, and the oxygen consumption fell to 41% of the initial values. After treatment with the shed blood, the flow in the hepatic artery and portal vein returned to preshock values, and the oxygen consumption was 39% higher than the initial values. After dextran 40 treatment, the flow in the hepatic artery was 91% higher than the initial value and the flow in the portal vein was 127% higher. In spite of these high flow values, the oxygen consumption was significantly lower in the dextran 40 group. In the second period of shock, flow values were reduced to approximately the same values as in the first period, but the oxygen consumption was significantly lower in the dextran 40 group than in the blood transfusion group. The hepatic circulation during shock is different in the pig compared with that in the dog and cat.

0898 THE ENHANCEMENT OF ADENYL CYCLASE BY STEROID THERAPY IN SHOCK.

(Eng.) Jones, C. A.; McArdle, A. H.; Hinchey, E. J. (Montreal General Hosp., Montreal, Quebec H3G 1A4, Canada). *Surgery* 82(4):483-488; 1977.

Experiments were carried out in dogs to study the normal response of the second messenger system in splanchnic tissues to hormonal stimulation and to determine whether the hormonal response is altered by hemorrhagic shock. Hepatic and intestinal adenyl cyclase (AC) activity were measured after a single pulse injection of epinephrine (0.25 mg, i.v.) or glucagon (0.3 mg, i.v.) into normal dogs and into dogs subjected to hemorrhagic shock. Hemorrhagic shock abolished the increase in AC activity seen in normal animals following epinephrine and significantly reduced that induced by glucagon. These changes were reflected in the glucose production from the liver induced by these hormones. The response of AC to the *in vitro* addition of epinephrine or glucagon, as well as the nonspecific stimulator of AC, sodium fluoride, showed that it is the receptor site of the enzyme that is primarily affected by shock. The treatment of dogs with 30 mg/kg of methylprednisolone following the reinfusion of shed blood significantly improved the response of AC to epinephrine in both liver and intestine, and this improvement was reflected in the glucose production by the liver in response to the hormone. The hormonal sensitivity of the splanchnic second messenger system, which is reduced significantly in shock, appears to be markedly improved by the administration of pharmacological doses of steroids.

0899 CHANGES IN CARDIAC OUTPUT DISTRIBUTION AFTER LIVER DEARTERIALIZATION IN THE RAT.

(Eng.) Lindell, B.; Aronsen, K. F. (Malmo General Hosp., Malmo, Sweden). *Acta Chir. Scand.* 143(4):207-213; 1977.

The changes in cardiac output distribution were studied in male Wistar rats after hepatic artery ligation and additional ligament division. These procedures resulted initially in a marked decrease in the arterial blood supply to the liver, and this effect was still pronounced 4 weeks after the operation. The decrease in liver blood supply induced by the procedure was in part counterbalanced by arteriovenous shunting in the preportal region. A temporary redistribution of cardiac output with reduced fractions to colon and spleen was found 2 weeks after these operations; this finding may have been a result of diversion of arterial blood through arteriovenous shunts.

0900 MORPHOLOGICAL ALTERATIONS AND FUNCTIONAL CHANGES OF INTERHEPATOCELLULAR JUNCTIONS INDUCED BY BILE DUCT LIGATION.

(Eng.) Metz, J.; Aoki, A.; Merlo, M.; Forssmann, W. G. (Anatomisches Institut der Universitat, Im Neuenheimer Feld 307, D-6900 Heidelberg, W. Germany). *Cell Tissue Res.* 182(3):299-310; 1977.

The effect of bile duct ligation on the intercellular junctions of hepatocytes was investigated in male Wistar rats. The features and the arrangement of the bile canaliculi and the zonulae occludentes were altered 48 hr after ligation, which caused an increase in intracanalicular pressure. The lumina of the bile canaliculi enlarged, and the microvilli disappeared. The array of the zonulae occludentes became irregularly shaped, the number of strands diminished, and interruptions of the strands occurred. One minute after the i.v. injection of horseradish peroxidase (10 mg/100 g), a leakage in the bile-blood barrier was detected. The gap junctions between the hepatocytes disappearec after bile duct ligation. The results show that the zonulae occludentes are mobile structures that are changed by increased unilateral pressure. Due to their ultrastructural alterations, a leakage of the permeability barrier between physiological compartments occurs.

0901 CONTROL OF LIVER SIZE IN HEAT-ACCLIMATED HAMSTERS.

(Eng.) Chayoth, R.; Krauthammer, N.; Winikoff, J.; Sod-Moriah, U. A. (Dept. Biology, Ben Gurion Univ. of the Negev, Beer Sheva, Israel). *J. Appl. Physiol.* 43(3):445-448; 1977.

To determine whether the decreased liver size seen in hamsters exposed to high ambient temperatures is controlled by cyclic AMP, or by other factors, the activity of DNA synthesis was correlated with cyclic AMP levels in the livers of hamsters maintained in a hot environment (35 ± 1 C) and of controls, maintained at 22 ± 1 C. In the heat-exposed animals, liver weight decreased more than did body weight. Therefore, liver weight constitutes a lower percentage of body weight during exposure to high ambient temperature. This change was not a result of dehydration, since water content of the whole body and of the liver was not altered during heat acclimation. However, changes in lactic dehydrogenase isozyme proportions indicated a higher rate of liver degradation during the first 2 weeks of heat exposure. These changes were accompanied by enhancement of DNA synthesis, which was elevated during the early period of heat exposure and later fell to the control levels. The enhanced DNA synthesis might be a result of a high rate of tissue regeneration, which probably takes place in the organ following the commencement of the degradative processes. Since the activity of DNA synthesis was negatively correlated with cyclic AMP levels, it is suggested that cyclic AMP plays some role in controlling hepatic DNA synthesis during heat acclimation.

0902 INFUSION TOMOGRAPHY OF THE GALLBLADDER: MECHANISM OF GALLBLADDER WALL OPACIFICATION IN EXPERIMENTAL ACUTE CHOLECYSTITIS.

(Eng.) Moncada, R.; Cardoso, M.; Danley, R.; Rodriguez, J.; Kimura, K.; Pickleman, J.; Brandly, J. (Loyola Univ. Medical Center, Maywood, IL 60153). *Am. J. Roentgenol.* 129(4):587-590; 1977.

A canine model of acute cholecystitis was used to determine the mechanism of opacification of the gallbladder wall by infusion tomography. The dogs underwent cystic duct ligation or cystic duct and cystic artery ligation. About 48 hr later, ^{125}I-labeled meglumine and sodium diatrilzoate were infused i.v. to a dose of 2.2 ml/kg. In normal gallbladders, the majority of the radioactivity was demonstrated within the blood vessels. There was no radioactivity in the extravascular spaces. A large proportion of the active contrast material had been taken up within polymorphonuclear granulocytes. In inflamed gallbladders, there was also some radioactive contrast material in the vascular spaces. In the extravascular space, contrast material was present exclusively within polymorphonuclear granulocytes. Some of these WBC may have come out of the vessels due to vessel disruption, as hemorrhage was seen in a few acutely inflamed gallbladders. However, even when the vessels maintained their integrity, WBC containing contrast material were seen in the edematous walls, especially in the subserosa. The results indicate that in the normal gallbladder, labeled radiopaque contrast material remains within the blood vessels, where some is taken up by polymorphonuclear leukocytes. In the inflammed gallbladder, inflammatory cells containing labeled contrast material are found in the edematous tissues of the gallbladder wall. This, together with hyperemia and probably tissue-fluid equilibration of contrast material, seem to be responsible for the visualization of the gallbladder wall with infusion tomography.

0903 INCREASED BILIARY TREE PERMEABILITY PRODUCED IN RATS BY HEPATOACTIVE AGENTS.

(Eng.) Peterson, R. E.; Fujimoto, J. M. (Univ. Wisconsin, Center for Health Sciences, Madison, WI 53706). *J. Pharmacol. Exp. Ther.* 202(3):732-739; 1977.

Changes in recovery of [^{3}H]sucrose or [^{3}H]mannitol administered by retrograde intrabiliary injection were compared between control groups and groups of Sprague-Dawley female rats treated with various drugs. After retrograde intrabiliary injection with 23.4 µl of the test substance, the bile duct cannula was occluded for 0.5 and 6 min (first experiment) or 0.5 and 3 min (other experiments) before bile flow was restarted, and individual drops were collected. In comparing the dose-response effects of dehydrocholate, cholate (C), and taurocholate (TC), it was shown that C and TC reduced [^{3}H]mannitol recovery beyond levels that could be attributed to the choleretic effect of these compounds. Similarly, in rats in which bile flow was reduced by hypothermia (31 C), C and TC reduced [^{3}H]mannitol recoveries, whereas dehydrocholate had no effect on the recovery. The authors conclude that C and TC increased biliary tree permeability as seen by the increase in [^{3}H]mannitol absorbed from the biliary tree. Female rats treated with ethynylestradiol (EE, 0.4 and 4 mg/kg/day) for 4 days had a reduced rate of bile flow. Comparable reductions in bile flow were achieved by the i.v. infusion of indocyanine green or by hypothermia. Since at these reduced bile flows only EE treatment reduced recovery of the markers, the authors conclude that EE increased biliary tree permeability. Also, EE-treated animals were less sensitive to the choleretic response but were more sensitive to the permeability-enhancing effect of various doses of TC than were control animals.

0904 HEPATIC EXCRETION OF CHOLECYSTOPAQUES INTRODUCED INTO THE CANINE JEJUNUM.

(Eng.) Menuck, L.; Amberg, J. R.; Bates, M. (Dept. Radiology, Univ. California, San Diego, CA). *Invest. Radiol.* 12(1):106-108; 1977.

The biliary excretion of five oral cholecystopaques (calcium ipodate, sodium ipodate, sodium trypanoate, iocetamic acid, and iopanoic acid) was measured following their introduction into the jejunum of bile fistula dogs. The mean maximal iodine concentration in the bile ranged from 2.2 ± 0.55 mg/ml following a dose of 33 mg of iodine/kg of iopanoic acid to 12.9 ± 1.4 mg/ml after the same dose of sodium ipodate. Cumulative excretion at the end of 3 hr was over five times greater with sodium ipodate in comparison to ipoanoic acid. The ability of the more water-soluble media to pass through the unstirred water layer of the intestine may explain these data.

0905 TECHNETIUM-99m-LABELED N-(2,6-DIMETHYLPHENYLCARBAMOYLMETHYL) IMINODIACETIC ACID (Tc-99m HIDA): A NEW RADIOPHARMACEUTICAL FOR HEPATOBILIARY IMAGING STUDIES. (Eng.) Ryan, J.; Cooper, M.; Loberg, M.; Harvey, E.; Sikorski, S. (Univ. Maryland Hosp., 22 S. Greene St., Baltimore, MD 21201). *J. Nucl. Med.* 18(10):997-1004; 1977.

An easily formulated, stable kit preparation of technetium-99m-labeled *N*-(2,6-dimethylphenylcarbamoylmethyl) iminodiacetic acid (^{99m}Tc HIDA), suitable for use in humans, was developed and tested in mice and dogs. The tracer was cleared rapidly from the blood and excreted predominantly by the liver in both species. In dogs, the hepatobiliary clearance of ^{99m}Tc HIDA was significantly greater than that of ^{14}C HIDA and ^{113}Sn HIDA. The LD_{50} for HIDA in mice, 168 mg/kg, exceeded the average human dose by a factor of 1,000 on a per-weight basis. Blood clearance curves for ^{99m}Tc HIDA in 12 normal subjects were biexponential with half-times of 4.6 ± 1.0 min and 31.5 ± 7.0 min, and cumulative 90-min urine samples contained 14.2 ± 1.8% of the injected dose. Images in normal subjects and nonjaundiced patients showed rapid concentration of tracer by the liver, and activity was present within the biliary system in 10-20 min. In jaundiced patients, the tracer blood clearance was delayed and urinary excretion increased, but intestinal activity, indicating biliary patency, was imaged in those patients without complete focal obstruction of the common duct. ^{99m}Tc HIDA is a nontoxic radiopharmaceutical useful for clinical evaluation of hepatobiliary disorders in humans.

0906 INTERACTION OF BROMOSULFOPHTHALEIN WITH MITOCHONDRIAL MEMBRANES--INHIBITION OF RESPIRATION. (Eng.) Burr, R.; Schwenk, M.; Pfaff, E. (Inst. Toxicology, Univ. Tubingen, D-7400 Tubingen, W. Germany). *Biochem. Pharmacol.* 26(6):461-466; 1977.

The kinetics of mitochondrial respiratory inhibition produced by BSP were studied. BSP reversibly inhibited mitochondrial respiration. The most sensitive was state 3 respiration (Ki about 3 nmol/mg protein independent of substrate). At higher concentrations (20-100 nmol/mg protein), state 4 respiration and uncoupled respiration were also inhibited. This inhibition was substrate dependent. With succinate, inhibition appeared to be noncompetitive at low concentrations and competitive above 1 mM succinate (half-maximal inhibition at 9-17 nmol/mg protein, dependent on succinate concentration). Substrate permeation did not seem to be the only sensitive step in oxidation, as was deduced from similar results obtained on glycerol phosphate respiration. Using artificial electron shunts and difference spectroscopy, individual dehydrogenases were found to be probable sites of BSP action. It is suggested that BSP acts via the electrostatic effects of the increased negative surface charge, making dehydrogenases less accessible for their substrates.

0907 INHIBITION BY BROMSULPHTHALEIN OF THE BILIARY EXCRETION OF ITS GLUTATHIONE CONJUGATE. (Eng.) Gregus, Z.; Fischer, E.; Varga, F. (Univ. Medical Sch., Szigeti u. 12, H-7643 Pecs, Hungary). *Biochem. Pharmacol.* 26(20):1951-1952; 1977.

The importance of the competition between BSP and its glutathione conjugate (BSP-GSH) during the biliary excretion of the two substances was investigated in rats. The concentration of BSP in the liver was much higher than that of BSP-GSH. In bile duct-ligated rats, BSP-GSH proved to be a very weak inhibitor of the hepatic uptake of BSP. Similarly, BSP depressed the hepatic concentration of BSP-GSH significantly ($p<0.01$) only at a dose of 120 μmol/kg (as compared with a dose of 60 μmol/kg, i.v.). However, 60 μmol/kg of BSP did not affect the hepatic uptake of BSP-GSH, although the same dose of BSP markedly depressed the biliary excretion of BSP-GSH. These results suggest that competition between BSP and BSP-GSH for hepatic uptake may not be significant in the overall transport of BSP or BSP-GSH from blood to bile. BSP-GSH (60-120 μmol/kg) did not significantly depress the biliary excretion of BSP, but the excretion rate of BSP-GSH was markedly depressed by a dose as low as 15 μmol/kg of BSP. A significant inhibition of BSP-GSH excretion was observed in the first 15 min of bile collection with a simultaneous administration of 7.5 μmol/kg of BSP. The excretion of BSP-GSH in the following 30 min of bile collection masked this inhibition. The results indicate that the inhibitory effect of free BSP on BSP-GSH excretion may have an important role in the transport rate of total dye excretion.

0908 PHARMACOKINETIC ASPECTS OF SULFOBROMOPHTHALEIN TRANSPORT IN CHRONICALLY CARBON TETRACHLORIDE-INTOXICATED RATS. (Eng.) Iga, T.; Sugiyama, Y.; Yokota, M.; Tomono, Y.; Awazu, S.; Hanano, M. (Faculty Pharmaceutical Sciences, Univ. Tokyo, Bunkyo-ku, Tokyo 113, Japan). *Biochem. Pharmacol.* 26(20):1867-1875; 1977.

To elucidate the factors affecting the hepatic transport of BSP in pathological conditions, the kinetics (i.e., binding activities of plasma and hepatic cytoplasmic proteins, and glutathione S-transferase activity of the Y-fraction) of the BSP disappearance from the blood and appearance in the bile were studied in rats chronically intoxicated with carbon tetrachloride (0.1 ml/100 g, s.c., twice weekly, 8-9 weeks). Although plasma protein albumin concentration decreased during chronic intoxication, no quantitative difference was shown in the high affinity binding site (K_1). A significant decrease was shown in the cytoplasmic protein concentration for the Y- and Z- fractions in intoxicated rats; no significant difference was observed in the number of binding sites for both fractions, but their binding constants decreased. Glutathione S-transferase activity and glutathione (GSH) content were not altered, although a decrease in conjugating activity per rat was expected. The time course for the plasma disappearance and biliary excretion of BSP showed a remarkable delay after CCl_4 intoxication, while no difference was shown in the bile flow rate. It is concluded that hepatic blood flow might play a primary role in the initial plasma disappearance of BSP and that the decrease in the Y-fraction binding activity might explain the decrease in BSP uptake rate into the liver that was observed in intoxicated rats.

0909 TRANSFER AND REOXIDATION OF REDUCING EQUIVALENTS AS THE RATE-LIMITING STEPS IN THE OXIDATION OF ETHANOL BY LIVER CELLS ISOLATED FROM FED AND FASTED RATS.

(Eng.) Cederbaum, A. I.; Dicker, E.; Rubin, E. (Mount Sinai Sch. Medicine, City Univ. New York, New York, NY 10029). *Arch. Biochem. Biophys.* 183(2):638-646; 1977.

Factors regulating the oxidation of ethanol were studied in liver cells isolated from fed and fasted Sprague-Dawley rats. The rate of ethanol oxidation was greater in liver cells from fed rats than from fasted rats. Inhibitors of the malate-aspartate shuttle decreased the rate of ethanol oxidation, suggesting that this shuttle contributes to the reoxidation of cytosolic NADH produced during the oxidation of ethanol. The greater inhibition of ethanol oxidation by antimycin than by rotenone suggested that the α-glycerophosphate shuttle also plays an important role in transporting reducing equivalents. The components of the malate-aspartate and α-glycerophosphate shuttles stimulated ethanol oxidation to a greater extent in liver cells from fasted rats than those from fed rats, suggesting that in the fasted state ethanol oxidation is regulated by the intracellular concentrations of substrate shuttle components, which transfer reducing equivalents into the mitochondria. Therefore, uncoupling agents, which stimulate oxygen consumption, do not stimulate ethanol oxidation, and concentrations of antimycin that depress oxygen uptake are much less effective in decreasing ethanol oxidation. By contrast, in liver cells from fed rats, the rate of ethanol oxidation was increased by uncoupling agents. Such stimulation was not observed when cells were prepared in the absence of albumin, probably due to leakage of shuttle substrates that leads to abnormally low intracellular levels. When the shuttle substrates were added back to these preparations, uncouplers were effective in stimulating the rate of ethanol oxidation beyond the stimulation produced by the shuttle substrates alone. Thus, under conditions of sufficient intracellular levels of the intermediates of the substrate shuttles, ethanol oxidation is regulated by the capacity of the mitochondrial respiratory chain to reoxidize reducing equivalents generated by the alcohol dehydrogenase reaction.

0910 THE EFFECTS OF ACUTE ETHANOL FEEDING AND OF CHRONIC BENFLUOREX ADMINISTRATION ON THE ACTIVITIES OF SOME ENZYMES OF GLYCEROLIPID SYNTHESIS IN RAT LIVER AND ADIPOSE TISSUE.

(Eng.) Pritchard, P. H.; Bowley, M.; Burditt, S. L.; Cooling, J.; Glenny, H. P.; Lawson, N.; *et al.* (Univ. Hosp. and Medical Sch., Clifton Blvd., Nottingham NG7 2UH, England). *Biochem. J.* 166(3):639-642; 1977.

The effects of ethanol and of 1-(3-trifluoromethylphenyl)-2-[*N*-(2-benzoyloxyethyl)amino]propane or S-780 (benfluorex) on the activities of some of the enzymes of glycerolipid synthesis were investigated in the livers and adipose tissue of male Wistar rats. The rats were treated for 5 days with benfluorex (50 mg/kg) or with suspending medium (controls). They were then intubated with an acute intoxicating dose of ethanol (5 g/kg) or with glucose of equivalent energy content. Ethanol treatment of the control rats that had not received benfluorex specifically increased the hepatic activity of the soluble phosphatidate phosphohydrolase by about fivefold in 6 hr. The equivalent increase in the benfluorex-treated rats was about twofold. The activities of the other enzymes tested (liver glycerol phosphate acyltransferase; microsomal phosphatidate phosphohydrolase, phosphatidate cytidylyltransferase, choline phosphotransferase, and diacylglycerol acyltransferase; and adipose glycerol phosphate acyltransferase, total phosphatidate phosphohydrolase, ATP-+Coenzyme A-dependent synthesis of acylalkylglycerol, and ATP-+Coenzyme A-dependent synthesis of acylalkylglycerol from hexadecylglycerol) were not significantly altered. The results are compatible with the hypothesis that changes in the activity of the soluble phosphatidate phosphohydrolase contribute to the control of the metabolism of fatty acids and to their incorporation into hepatic triacylglycerols.

0911 EFFECTS OF CLOFIBRATE ON ETHANOL-INDUCED MODIFICATIONS IN LIVER AND ADIPOSE TISSUE METABOLISM: ROLE OF HEPATIC REDOX STATE AND HORMONAL MECHANISMS.

(Eng.) Savolainen, M. J.; Jauhonen, V. P.; Hassinen, I. E. (Dept. Medical Biochemistry, Univ. Oulu, Kajaanintie 52 A, SF-90220 Oulu 22, Finland). *Biochem. Pharmacol.* 26(5):425-431; 1977.

Mechanisms by which clofibrate decreases the development of acute alcoholic fatty liver were studied in rats, especially in regard to hepatic redox state and hormonal regulation of carbohydrate and lipid metabolism. A partial inhibition of the ethanol-induced increase in cytosolic NADH/NAD ratio was observed. As a result, in clofibrate-treated rats (600 mg/kg/day, 9 days, s.c.) hepatic sn-glycerol-3-phosphate (α-GP) concentration during ethanol oxidation also remained at the same level as in normal control rats. Clofibrate treatment prevented the ethanol-induced increase in the adipose tissue cyclic AMP and plasma free fatty acid concentrations. Hepatic concentrations of coenzyme A (Co-A)-SH, acetyl-CoA, and long-chain acyl-CoA were markedly increased by clofibrate treatment. Plasma insulin concentration was decreased in clofibrate-treated rats, which also showed an impaired glucose tolerance. The results show that clofibrate is able to restrict the availability of substrates (α-GP and fatty acids) for hepatic triglyceride synthesis *in vivo*. In addition, it is concluded that the partial inhibition of ethanol-induced fatty liver by clofibrate may result from the enhancement of the oxidation pathway of fatty acid metabolism, as suggested by the enormous increase in hepatic content of CoA-SH and its derivatives.

0912 THE MECHANISM OF ENHANCEMENT OF RAT LIVER TRYPTOPHAN PYRROLASE ACTIVITY BY ACUTE ETHANOL ADMINISTRATION.
(Eng.) Badawy, A. A. B.; Evans, M. (Univ. Hosp. Wales, Cardiff CF4 7XB, Wales). *Biochem. Soc. Trans.* 5(4):1035-1036; 1977.

The mechanism by which rat liver tryptophan pyrrolase activity is enhanced by acute ethanol administration was investigated by determining the half-life of the enzyme after acute ethanol administration (5 ml/kg, i.p. as a 25% volume/volume solution) in intact male Wistar rats. Ethanol significantly ($p<0.001$) enhanced the holoenzyme and total pyrrolase activities by 2.35- and 1.78-fold, resp., and increased the ratio of holoenzyme/apoenzyme activity from a control value of 0.74 to 1.45. The half-life of the total enzyme in ethanol-treated rats was 3.94 hr, which represented a 73% increase in the stability of the pyrrolase by ethanol. This finding provides further support for the involvement of tryptophan in the ethanol effect.

0913 THE MECHANISM OF INHIBITION OF RAT LIVER TRYPTOPHAN PYRROLASE ACTIVITY BY CHRONIC ETHANOL ADMINISTRATION.
(Eng.) Evans, M.; Badawy, A. A. B. (Univ. Hosp. Wales, Cardiff CF4 7XB, Wales). *Biochem. Soc. Trans.* 5(4):1037-1038; 1977.

The mechanism by which the chronic administration of ethanol inhibits rat liver tryptophan pyrrolase activity was investigated by determining the effect of chronic ethanol, sucrose, or water treatment on cortisol-induced pyrrolase activity. Male Wistar rats received one of the following three drinking fluids for 28-31 days: water, sucrose (9%, weight/volume), or ethanol (5% volume/volume for 2 days, 7.5% for 2 further days, and 10% thereafter). Some rats also received cortisol acetate (20 mg/kg, i.p.) 4 hr before sacrifice. Chronic ethanol or sucrose administration inhibited the total pyrrolase activity by 35% but had no effect on that of the holoenzyme; the apoenzyme was therefore the form specifically inhibited by either treatment (by 80%, $p<0.001$). Cortisol was equally effective in inducing the enzyme activity in both chronic ethanol-treated and control rats, suggesting that ethanol does not inhibit the synthesis of the apoenzyme. The cortisol effect in rats treated chronically with sucrose was, however, lower by 24-34% than that in controls. The results suggest that sucrose is not a suitable control treatment in studies of the effects of ethanol on liver or brain tryptophan metabolism.

0914 IN VIVO STUDIES OF AMINO ACID METABOLISM IN RAT INTESTINE AND LIVER.
(Fre.) Demigne, C.; Aufrere, J.; Remesy, C. (Station de Physiopathologie de la Nutrition, I.N.R.A., Theix, Saint Genes Champanelle, 63110 Beaumont, France). *Ann. Biol. Anim. Biochim. Biophys.* 17(4):615-620; 1977.

Liver uptake and intestinal metabolism of amino acids in rats during absorption of a diet high in casein (13%) was studied. The diet fed to Sherman rats, conditioned to absorb their food in 8 hr, consisted of 79% wheat starch, 2% corn oil, 5% minerals, and 1% vitamins in addition to the casein. Animals were anesthetized with Nembutal (40 mg/kg, s.c.) 4 hr after they began eating, and blood was removed for amino acid analysis from the portal vein and artery or from the hepatic and portal veins. Livers were then removed, minced, and centrifuged. Alanine in the portal vein came from casein hydrolysis, from transamination of glutamic and aspartic acids in the intestinal cells, and from deaminated glutamine. Amino acid release into the portal vein was compared with overall liver balance, taking into account the flow rate of the hepatic artery. The uptake of alanine, glycine, and aromatic amino acids by the liver was high (78%, 82%, and 64-70% of the total alanine, glycine, and aromatic acids in the administered casein, resp.), while that of serine and threonine was low (49% and 43%, resp.). Only a small fraction of branched-chain amino acids was taken up by the liver (about 20%); the main uptake of these occurred in the periperhal tissues.

0915 THE ISOLATION AND FURTHER CHARACTERIZATION OF THE BILIRUBIN TETRAPYRROLES IN BILE-CONTAINING HUMAN DUODENAL JUICE AND DOG GALL-BLADDER BILE.
(Eng.) Gordon, E. R.; Chan, T. H.; Samodai, K.; Goresky, C. A. (Montreal General Hosp., 1650 Cedar Ave., Montreal, Quebec H3G 1A4, Canada). *Biochem. J.* 167(1):1-8; 1977.

A simple reproducible method for the isolation of the native bilirubin tetrapyrroles from bile-containing human duodenal juice and dog gallbladder bile is described, and the tetrapyrroles are further characterized. Bilirubin and its conjugates are extracted from bile or bile-containing duodenal juice into chloroform containing 10 mM tetraheptylammonium chloride. The intact bilirubin tetrapyrroles are then separated by thin-layer chromatography. Structural elucidation was made after coupling of the individual pigments with diazonium salts. Four azopigments were detected: azopigment α_0 or dipyrrolic azobilirubin, azopigment δ or dipyrrolic azobilirubin monoglucuronide, azopigment α_3 or dipyrrolic azobilirubin monoglucoside, and, from dog gallbladder bile, azopigment α_2. The last conjugate required further verification of its structure. After methanolysis, it was shown by combined gas-liquid chromatography-mass spectrometry to contain xylose in a 1:1 molar ratio with the azopigments of bilirubin. Human bile contained 86% bilirubin monoglucuronide, 7% bilirubin monoglucuronide monoglucoside diester, 4% bilirubin monoglucuronide, and 3% bilirubin. Dog gallbladder bile had a considerably different composition; it contained 47% bilirubin diglucuronide, 40% bilirubin monoglucuronide monoglucoside diester, 8% bilirubin monoglucuronide, 4% bilirubin diglucoside, 1-2% bilirubin, and traces of conjugates containing xylose. The total bilirubin content and proportions of the conjugates did not change in bile that was frozen and stored at -20 C under N_2, whereas in the chloroform/tetraheptylammonium chloride extract, similarly stored, total pigment was slowly lost and the diglucuronide conjugate converted into the monoglucuronide.

0916 SYNTHESIS AND ENTEROHEPATIC CIRCULATION OF BILE SALTS. (Eng.) Hanson, R. F.; Pries, J. M. (Univ. Minnesota Hosp., Minneapolis, MN). *Gastroenterology* 73(3):611-618; 1977.

A review is presented of the present knowledge of bile salt synthesis, secretion, absorption by the intestine, and removal by the liver. The pathways for bile salt synthesis, bile acid conjugation, and sulfation, and the role of carrier proteins in bile acid synthesis are discussed. Interaction of bile salts with hepatic enzymes such as 3-hydroxy-3-methylglutaryl-CoA reductase, 7-hydroxylase, and 12-hydroxylase is reviewed. It is suggested that the uptake of bile salts is mediated by a Na$^+$-dependent carrier transport mechanism.

0917 SEX-LINKED DIFFERENCES IN BILE ACID METABOLISM OF GERMFREE RATS. (Eng.) Eyssen, H.; Smets, L.; Parmentier, G.; Janssen, G. (Rega Inst. Medical Res., Univ. Leuven, Minderbroedersstraat 10, B-3000 Leuven, Belgium). *Life Sci.* 21(5):707-712; 1977.

To investigate the influence of sex on bile acid composition, sulfated and unsulfated bile acids were quantitated in male and female germfree rats. Gas chromatography and mass spectrometry revealed that β-muricholic acid and cholic acid were the major bile acids in both sexes; in addition, 3β-hydroxy-5-cholenoic acid, chenodeoxycholic acid, α-muricholic acid, allochenodeoxycholic acid, and allocholic acid were present. β-Muricholic and cholic acids accounted for 61.4% and 22.7%, resp., of total bile acids in the small intestine of males; females had 38.9% of β-muricholic acid and 50% of cholic acid. In females, the bile acid sulfate fraction increased from 1.1% in the small intestine to 22.3% in the large intestine; in males these values were 0.2% and 1.7%, resp. A considerable increase in the relative amounts of allochenodeoxycholic and allocholic acids was observed in the cecum and large intestine of the female rat, where more than 70% of these substances was in the bile acid sulfate fraction. In males, these allo-bile acids were mainly in the unsulfated fraction, and their relative amounts did not increase in the large intestine. This study shows important sex-linked differences in the relative amounts and sulfation of bile acids in germfree rats.

0918 BILE ACID BINDING BY 100 000 g SUPERNATANTS FROM RAT LIVER. (Eng.) Strange, R. C.; Nimmo, I. A.; Percy-Robb, I. W. *In: Bile Acid Metabolism in Health and Disease. Proceedings of the IV Bile Acid Meeting held at the Hilton Hotel, Basel, Switzerland, October 11-12, 1976.* University Park Press (Baltimore, MD): 125-132; 1977.

The binding of cholic acid, glycocholic acid, chenodeoxycholic acid, and lithocholic acid to rat liver 100,000 x *g* supernatants was demonstrated using equilibrium dialysis. Rectangular hyperbolae fitted the binding data for chenodeoxycholic acid, lithocholic acid, and glycocholic acid, suggesting that binding could be explained in terms of single saturable components. The binding data for cholic acid were better fitted by a straight line plus a rectangular hyperbola, suggesting the presence of at least two different types of binding sites. The binding characteristics of the bile acids suggest that the binding components are involved in bile acid transport. When mixtures of [^{14}C]lithocholic acid and liver supernatants were eluted from columns of Sephadex G-75, a prominent peak of [^{14}C]lithocholic acid appeared with proteins of molecular weight approximately 40,000. A second, smaller peak of [^{14}C]lithocholic acid was eluted with proteins of molecular weight approximately 10,000.

0919 HYDROXYLATIONS IN BIOSYNTHESIS AND METABOLISM OF BILE ACIDS CATALYZED BY RECONSTITUTED SYSTEMS FROM RAT LIVER MICROSOMES. (Eng.) Cottman, J.; Danielsson, H.; Hansson, R.; Wikvall, K. *In: Bile Acid Metabolism in Health and Disease. Proceedings of the IV Bile Acid Meeting held at the Hilton Hotel, Basel, Switzerland, October 11-12, 1976.* University Park Press (Baltimore, MD): 1-10; 1977.

Several hydroxylations in the biosynthesis and metabolism of bile acids were studied in reconstituted systems from rat liver microsomes consisting of cytochrome P-450 and NADPH-cytochrome P-450 reductase at different stages of purification. A partial separation of 5β-cholestane-3α,7α-diol 12α- and 26-hydroxylase activities was obtained by polyethylene glycol fractionation of cholate-solubilized cytochrome P-450 followed by diethylaminoethyl (DEAE)-cellulose chromatography. These two hydroxylase activities differed not only from each other but also from other hydroxylase activities such as taurodeoxycholate 7α-hydroxylase activity and laurate 11- and 12-hydroxylase activities. Cholesterol and cholestanol 7α-hydroxylase activity was compared with 5β-cholestane-3α,7α-diol 12α- and 26 hydroxylase activities. By polyethylene glycol and ammonium sulfate fractionation, a partial separation of these three activities was obtained. The possibility that some specificity also resided in the NADPH-cytochrome P-450 reductase was tested with reductase preparations of different purity. In contrast to several other hydroxylations including 12α-hydroxylation of 5β-cholestane-3α,7α-diol, 26-hydroxylation of 5β-cholestane-3α,7α,12α-triol and 7α-hydroxylation of taurodeoxycholic acid, which were all stimulated by the different preparations, 25-hydroxylation of 5β-cholestane-3α,7α,12α-triol and 7α-hydroxylation of cholesterol were stimulated to a greater extent by the less pure preparations than by the purer preparations. The results indicate the participation of several cytochromes P-450 in the hydroxylations occurring in bile acid biosynthesis and metabolism and point to the possibility that other factors present in less pure preparations of NADPH-cytochrome P-450 reductase also may play a role in imparting specificity to the hydroxylations.

0920 EXPERIMENTAL CHOLESTASIS BY DIBUCAINE AND HARMALINE: EFFECTS ON BILE FLOW AND HEPATIC TRANSPORT OF BILE ACIDS, ETHACRYNIC ACID AND OUABAIN. (Ger.) Peterlik, M. (Institut fur allgemeine und experimentelle Pathologie, Universitat Wien, Wahringer Strasse 13, A-1090 Vienna, Austria). *Wien. Klin. Wochenschr.* 89(14):494-501; 1977.

Dibucaine- and harmaline-induced experimental cholestasis and the effects of these substances on bile secretion and active transport of bile acids, ethacrynic acid and ouabain were studied in the isolated liver of adult Sprague-Dawley rats. Both dibucaine (0.5-1.6 mM) and harmaline (1.7-4 mM) inhibited bile secretion; a nearly linear dose-dependence effect was found for both substances. The effect of dibucaine was fully reversible, but bile secretion failed to reach the normal level after inhibition with harmaline at the highest concentration (4 mM), which may indicate partially irreversible damage of the secretory function of the liver. Both substances caused only a slight reduction in the oxygen consumption of the isolated liver. While typical signs of intrahepatic cholestasis (dilatation of the canaliculi) were seen, the ultrastructure of the liver was completely intact, and no signs of nonspecific liver damage (swelling of mitochondria or of the endoplasmic reticulum) were seen, which indicates that the cholestasis was not due to a nonspecific hepatotoxic effect. The transport of taurocholic acid into the isolated liver was influenced only slightly by dibucaine (1.6 mM) and harmaline (4 mM), but dibucaine inhibited the influx of cholic acid, ethacrynic acid, and ouabain by 60%, 58%, and 90%, resp., and harmaline caused inhibitions by 60%, 82%, and 86%, resp. The findings indicate that harmaline and dibucaine inhibit taurocholate transfer only to the extent of the Na^+-dependent fraction, and that drug-membrane interactions, primarily on the sinusoidal surface, but possibly also at the canalicular pole of the hepatocytes, are responsible for the impairment of basal and stimulated bile secretion. The perfusion model is suitable for the experimental study of intrahepatic cholestasis, of the influence of the hepatocyte membrane functions on canalicular bile secretion, and of the possible pathogenetic role of these functions in intrahepatic cholestasis.

0921 GLUCOCORTICOID INFLUENCE ON MORPHOLOGICAL DIFFERENTIATION AND BILE ACID METABOLISM IN RAT LIVER CELL CULTURE. (Eng.) Lambiotte, M. *In: Bile Acid Metabolism in Health and Disease. Proceedings of the IV Bile Acid Meeting held at the Hilton Hotel, Basel, Switzerland, October 11-12, 1976.* University Park Press (Baltimore, MD): 33-47; 1977.

The influence of dexamethasone (dex) on morphological differentiation and bile acid metabolism was studied in primary cell cultures of rat fetal liver, in monolayers of adult rat hepatocytes, and in a cloned strain of a cultivated "minimal deviation" rat hepatoma. Labeled cholic or deoxycholic acid (51 and 52 mCi/mmol, resp.) were added to the cultures, and the various metabolites appearing in the medium were tentatively determined using thin-layer chromatography (TLC), scanning, and autoradiography. In fetal liver cultures, dex (1.9×10^{-6} M) induced the appearance of bile canaliculi after 3 or 4 days, towards which the hepatocytes seemed to retain some polarity. Cholate and deoxycholate were conjugated mainly to taurine, with traces of glycine conjugates in the treated group; the conjugation was retained longer in the presence of dex. Deoxycholate was partially transformed into taurocholate, free cholate, and traces of glycocholate, but the hydroxylation was hardly noticeable in controls. The adult hepatocyte monolayers remained healthy longer in the presence of dex, whereas cells in the control cultures degenerated in 4-6 days. In the two experimental groups, deoxycholate was transformed into taurocholate, taurodeoxycholate, glycocholate, glycodeoxycholate, and free cholate. The proportion of glycine conjugates was higher than in the fetal liver culture, especially in the control group, and the hydroxylation products were more abundant in the presence of dex. In the hepatoma monolayers, cholate conjugation was obtained after only 2 days in dex, and deoxycholate conjugation was markedly increased by the hormone. Deoxycholate hydroxylation was noticed only in the treated plates; the main induced product had a relative front in TLC migration intermediate between glycocholate and glycodeoxycholate. The results provide good evidence for a glucocorticoid induction, not only of bile excretory pathways, but also of the 7α-hydroxylation system of deoxycholic acid, which could be important *in vivo* during the functional maturation of rat fetal liver.

0922 THE HEPATOTOXICITY OF LITHOCHOLIC ACID IN MALE MICE. (Eng.) Taylor, W.; Lesna, M. (Medical Sch., Univ. Newcastle upon Tyne, Newcastle upon Tyne NE1 7RU, England). *Br. J. Pharmacol.* 61(1):133P-134P; 1977.

The mechanism by which lithocholic acid (LA) causes intrahepatic cholestasis and early damage to the bile canaliculi in rodents was studied in Balb/c mice by determining the cholesterol and bile acids in the gallbladder bile and by observing the development of hepatic lesions after the administration of LA (8 mg/day by gavage). Cholesterol was determined colorimetrically, and bile acids by gas chromatography-mass spectrophotometry, in animals killed 0.5, 1.5, 2.5, and 3.5 days after the start of treatment. The biliary cholesterol concentrations rapidly increased while total bile acids first increased and then decreased, causing a dramatic decrease in the total bile acid/cholesterol ratio. Between 1.5 and 2.5 days there was a large decrease in cholic acid concentration in the bile; both LA and 3α,6β-dihydroxy-5β-cholanoic acid, which were not detectable in control bile, appeared in increasing amounts. These changes preceded the appearance of liver damage, which was well established after 2.5 days. The livers of LA-treated animals showed necrotic areas of irregular distribution with some dilatation of centrilobular venules and inflammatory and neutrophil infiltration. LA may exert its hepatotoxic effect in mice by altering hepatic cholesterol and bile acid biosynthesis.

0923 BILE ACID CONTROL OF BILIARY CHOLESTEROL SECRETION IN MAN.

(Eng.) Schersten, T.; Lindblad, L. *In: Bile Acid Metabolism in Health and Disease. Proceedings of the IV Bile Acid Meeting held at the Hilton Hotel, Basel, Switzerland, October 11-12, 1976.* University Park Press (Baltimore, MD): 175-181; 1977.

The interrelationships between biliary cholesterol secretion and the secretion of bile acids and lecithin were studied during depletion of the bile acid pool and during duodenal administration of cholic or chenodeoxycholic acid (1.0 g/hr, 4 hr) in 13 patients 7-12 days after cholecystectomy for uncomplicated gallstone disease. The relation between bile acid and cholesterol secretion rates was curvilinear during bile acid pool depletion ($r=0.70$) and during cholic acid secretion ($r=0.86$). The lecithin secretion rate was significantly correlated to the secretion rate of cholesterol under all the experimental conditions. These correlations were stronger at low bile acid secretion rates giving bile supersaturation in cholesterol. The results suggest that the biliary secretion rate of lecithin plays a determining role for the mass of secreted cholesterol and that the importance of lecithin is different at different rates of bile acid secretion.

0924 NUTRITIONAL AND HORMONAL CONTROL OF LUNG AND LIVER FATTY ACID SYNTHESIS.

(Eng.) Kumar, S. (New Jersey Medical Sch., Newark, NJ 07103). *Arch. Biochem. Biophys.* 183(2):625-637; 1977.

The effect of a high-fructose diet on the levels of fatty acid synthesizing enzymes was investigated in male Sprague-Dawley rats, and extensive studies on the nutritional and hormonal control of fatty acid synthesis in the mammalian lung were carried out. During starvation and in streptozotocin-induced diabetes, the total activities of rat lung acetyl coenzyme A (CoA) carboxylase and fatty acid synthetase were reduced to one-third of the normal values. Refeeding the starved animals or the administration of insulin to diabetic animals restored the levels to the original values. The insulin effect was dose- and time-dependent. These data contrast with those in the liver, where a 30- to 50-fold depression of these enzymes was observed in the diabetic state, and the administration of insulin was actually followed by doubling of the activity over normal controls. A fat-free high-fructose diet (containing 60% fructose by weight) enhanced the activities of liver enzymes three- to sixfold over the values of controls on laboratory diet but had no effect on the lung enzymes. Long-term feeding of the fructose diet also increased the activities of liver enzymes from diabetic animals to twice the value of normal controls on laboratory diet. Insulin administration to fructose-fed diabetic animals restored the enzyme activities to those obtained with fructose-fed normal controls. However, the stimulation of lung enzymes of diabetic animals was effected either by fructose or by insulin. Antigen-antibody titrations and measurements of the rate of protein synthesis showed that the increased activity of the lung and liver fatty acid synthetase is due to enhanced content rather than increased specific activity. These data suggest that the effects of insulin or fructose on fatty acid synthesizing enzymes are mediated through intermediate(s) whose concentration is affected in the experimental diabetes. Furthermore, all tissues may not have stringent insulin requirements, since the lung enzymes can be stimulated by fructose alone.

0925 INCREASED LIVER CALCIUM AFTER CALCIUM OR MILK GAVAGE IN RATS.

(Eng.) Meyer, R. A., Jr.; Meyer, M. H. (Sch. Dentistry, Marquette Univ., 604 North 16th St., Milwaukee, WI 53233). *Experientia* 33(4):546-547; 1977.

Experiments were carried out in male SPD rats to determine whether there is a change in liver calcium content during times of known calcitonin secretion. The liver calcium level was raised significantly at 0.5 hr ($p<0.01$) and at 1 hr ($p<0.05$) after gavage with milk (2 ml/100 g) and at 1 and 2 hr ($p<0.05$ and 0.01, resp.) after gavage with 300 mM $CaCl_2$ (2 ml/100 g), in comparison with that in controls that received either sham gavage or a deionized water gavage. Plasma calcium and phosphate were not significantly altered by the milk gavage, but were significantly affected by $CaCl_2$ gavage. The lack of change in plasma calcium, liver weight, and extracellular fluid content indicated that the increased liver calcium seen after the milk meal must represent increased intracellular calcium. Since the increase in liver calcium for the whole liver (0.27 μmol/100 g body weight) was quite small relative to the calcium content of the milk gavage (60 μmol/100 g body weight), it seems that the liver is not an important storage site for plasma calcium and that physiological stimuli of calcitonin secretion do not result in as large an increase in liver calcium as reported following the injection of the hormone.

0926 LIVER ENZYME INDUCTION BY THE ANION EXCHANGER RESIN, DOWEX 1 x 2, IN THE RAT. (Eng.) Beyhl, F. E.; Granzer, E. (Hoechst AG., Postfach 800320, D-6230 Frankfurt am Main 80, W. Germany). *Experientia* 33(9):1194-1195; 1977.

The nature of bile acid sequestration by the anion exchange resin, Dowex 1 x 2, was investigated by determining whether it induces the biosynthesis of microsomal drug metabolizing liver enzymes in male Wistar rats. The rats received the resin (500 mg/kg/day) by stomach tube for 8 days. This treatment led to liver enlargement and significant increases in liver acid phosphatase, glucose-6-phosphate dehydrogenase, malic enzyme, catalase, neotetrazolium reductase, NADPH:cytochrome c oxidoreductase, and aminopyrin demethylase ($p<0.001$, $p<0.001$, $p<0.0005$, $p<0.0005$, $p<0.0005$, $p<0.005$, and $p<0.0005$, resp.). The mitochondrial enzymes, glutamate and succinate dehydrogenases; mitochondrial cytochrome c reductase; and most of the soluble enzymes, α-glycerophosphate, malate, isocitrate, and 6-phosphogluconate dehydrogenases and the transaminase, were unchanged. Therefore, Dowex 1 x 2 treatment does not influence mitochondrial and cytosolic metabolisms, or at most, only parts of them. The sequestration of bile acids by anion exchange resin treatment with Dowex 1 x 2 mimics the biochemical effects of clofibrate- and phenobarbital-like drugs in the liver.

0927 THE EFFECT OF LEVAMISOLE ON PHOSPHODIESTERASE ACTIVITY. (Eng.) Constantopoulos, A.; Kafasi, V.; Doulas, N.; Liakakos, D.; Matsaniotis, N. (Aghia Sophia Children's Hosp., Athens, Greece). *Experientia* 33(3):395-396; 1977.

To determine whether levamisole acts by modifying nucleotide levels through activation of phosphodiesterase, the activity of this enzyme was estimated in mouse liver homogenates in the presence and absence of levamisole (10^{-2}-10^{-7} M). Phosphodiesterase activity was 1,394 and 1,399 nmol/mg protein/30 min in the presence and absence of the anthelmintic drug, resp. These data demonstrate that levamisole does not modify nucleotide levels via the activation of phosphodiesterase.

0928 DRY WEIGHT, TRIGLYCERIDES CONTENT AND GLUCOSE-6-PHOSPHATASE ACTIVITY OF HEPATOCYTES SEPARATED BY SEDIMENTATION. (Eng.) Tongiani, R.; Bibbiani, C.; Malvaldi, G. (Istituto di Patologia Generale, Universita degli Studi di Pisa, Scuola Medica, Via Roma 55, I-56100 Pisa, Italy). *Acta Histochem. (Jena)* 59(2):232-238; 1977.

Isolated rat hepatocytes were subfractionated by isopycnic or velocity sedimentation, and dry mass, triglycerides content, and glucose-6-phosphatase activity of different subpopulations were determined. The distribution of the cell dry masses and dry mass per average cell were similar in all the fractions separated by isopycnic sedimentation. Velocity sedimentation allowed a satisfactory separation of cells of different dry mass. Triglyceride content and glucose-6-phosphatase activity of cells of the different fractions obtained by isopycnic sedimentation showed no statistically significant differences. Subpopulations fractionated by velocity sedimentation differed in both triglyceride content and glucose-6-phosphatase activity, which were substantially parallel to the cell dry mass. Isopycnic sedimentation is not suitable for subfractionation of hepatocytes on the basis of their dry weight; this result can be achieved by velocity sedimentation.

0929 A COMPARISON OF EFFECT OF INSULIN ON HEPATIC METABOLITES, GLUCONEOGENESIS, AND KETOGENESIS. (Eng.) McDaniel, H. G. (Veterans Admin. Hosp., Birmingham, AL 35206). *Am. J. Physiol.* 233(1):E13-E18; 1977.

The effect of insulin on hepatic metabolites was studied in tryptophan-treated rats, and this effect was correlated with insulin-induced suppression of fatty acid oxidation and conversion of labeled lactate to glucose. In 12-hr fasted rats given tryptophan (25 mg/100 g, i.p.), insulin (10 U/kg, i.m.) decreased the hepatic content of alanine and the three precursors of oxalacetate (malate, citrate, and aspartate) while elevating hepatic pyruvate. These changes are consistent with suppression of the pyruvate carboxylase step. Animals fasted for 24 hr lose the effect on oxalacetate precursors, and this correlated with a loss of suppression of hepatic ketones. The decrease in hepatic alanine and oxalacetate precursors was more sensitive than the blood sugar. However, the conversion of labeled lactate to glucose was not inhibited by insulin in 12-hr fasted animals. (+)-Decanoylcarnitine also produced a decrease in oxalacetate precursors comparable to insulin and a lowering of the blood sugar. However, in fasted animals not given tryptophan it did not alter the blood sugar. Therefore, in tryptophan-treated animals alterations of fatty acid oxidation by insulin or (+)-decanoylcarnitine produce a fall in oxalacetate precursors consistent with inhibition of pyruvate carboxylase; however, this does not equate with overall suppression of gluconeogenesis by either of these agents in the absence of tryptophan.

0930 RESTORATION OF GLYCOGENESIS IN HEPATOCYTES FROM STARVED RATS. (Eng.) Geelen, M. J. H.; Pruden, E. L.; Gibson, D. M. (Lab. Veterinary Biochemistry, State Univ. Utrecht, Utrecht, Netherlands). *Life Sci.* 20(6):1027-1034; 1977.

Hepatocytes from rats starved for 48 hr were studied to define conditions that permit glycogen synthesis following the provision of metabolic precursors *in vitro*. Hepatocytes from the starved rats synthesized glycogen only when incubated in the presence of both glucose and glucogenic precursors (combinations of alanine, glycerol, pyruvate, lactate, or fructose). Unlabeled glucose increased the net flux of [U-^{14}C]alanine or [U-^{14}C]lactate into glycogen over 30-fold. Unlabeled lactate and alanine facilitated the incorporation of [U-^{14}C]-

glucose into glycogen, even though the basal level with glucose alone was relatively high, as compared to basal glucose incorporation. In systems containing no added endocrines, glucose dampened glycogen phosphorylase activity in a cyclic AMP-independent fashion. Fructose was unable to mimic the effects of glucose on glycogen deposition and on glycogen phosphorylase activity. The results suggest that with these liver cell preparations, it is possible to accumulate glycogen and to explore the early changes that ensue in the transition from the "glucogenic" state of liver metabolism in starvation to the "lipogenic" state in refeeding.

0931 THE EFFECTS OF EXPERIMENTAL INFLAMMATION ON ADAPTIVE SYNTHESIS OF RAT LIVER FATTY ACID SYNTHETASE. (Eng.) Shutler, G. G.; Langstaff, J. M.; Jamieson, J. C.; Burton, D. N. (Dept. Microbiology, Univ. Manitoba, Winnipeg, Manitoba R3T 2N2, Canada). *Arch. Biochem. Biophys.* 183(2):710-717; 1977.

The effects of experimental inflammation, induced by the s.c. injection of oil of turpentine (0.5 ml/100 g) on adaptive synthesis of liver fatty acid synthetase were investigated in male rats. Liver levels of α_1-acid glycoprotein, an "acute-phase" protein known to be synthesized at an accelerated rate as a result of inflammation, were also measured. The increase in fatty acid synthetase activity in livers of rats that were starved and then fed a fat-free diet was suppressed to an extent dependent on the periods between fat-free feeding and inflammation and inflammation and sacrifice. Inflammation induced 2 hr after refeeding gave complete suppression, whereas inflammation after 10 hr of fat-free feeding had no suppressive effect. When induced 2.5 or 7.5 hr after refeeding, inflammation led to partial suppression of the increase in fatty acid synthetase activity. The increase in liver α_1-acid glycoprotein levels characteristic of inflammation was reduced in animals inflamed 7.5 or 10 hr after fat-free feeding, but was unaffected when inflammation was induced 2.5 hr after refeeding. The ratio of free to membrane-bound polyribosomes in the liver increased from 0.77 in rats that were neither starved nor fed a fat-free diet to 3.31 in rats that were starved and then fed a fat-free diet for 15 hr. When inflammation was induced 2.5 hr after refeeding, the ratio increased to only 1.74 after 15 hr of refeeding. Inflammation resulted in a marked reduction in the level of glycogen in the liver, regardless of the time of induction of inflammation and the dietary status of the animal. The findings may be explained by changes in the activities of enzymes of glycogen metabolism, which lead to enhanced glycogenolysis in response to inflammation.

0932 EFFECTS OF OLEATE, PALMITATE, AND OCTANOATE ON GLUCONEOGENESIS IN ISOLATED RABBIT LIVER CELLS. (Eng.) Zaleski, J.; Bryla, J. (Inst. Biochemistry, Univ. Warsaw, 02-089 Warsaw, Poland). *Arch. Biochem. Biophys.* 183(2):553-562; 1977.

The effect of oleate, palmitate, and octanoate on glucose formation was studied in rabbit hepatocytes with lactate or pyruvate as substrate. Octanoate was much more quickly oxidized and utilized for ketone body production than were oleate and palmitate. Among the fatty acids studied, only octanoate resulted in a marked increase of the 3-hydroxybutyrate/acetoacetate ratio. Each of the fatty acids stimulated glucose synthesis from pyruvate. The enhancement of gluconeogenesis by long-chain fatty acids was abolished after the addition of ammonia. Examination of the "crossover" plot revealed that the stimulatory effect of fatty acids was due to (a) a stimulation of pyruvate carboxylation, (b) a provision of reducing equivalents for glyceraldehyde phosphate dehydrogenase, and (c) an acceleration of flux through hexose diphosphatase. Moreover, palmitate and oleate resulted in an increased generation of mitochondrial phosphoenolpyruvate, while in the presence of octanoate, the activity of mitochondrial phosphoenolpyruvate carboxykinase was diminished. When lactate was used as the glucose precursor, palmitate and oleate increased glucose production by about 50% but did not affect the contribution of mitochondrial phosphoenolpyruvate carboxykinase to gluconeogenesis. In spite of the stimulation of both pyruvate carboxylase and hexose diphosphatase, as judged from the crossover plot, the addition of octanoate resulted in a marked inhibition of both glucose formation and mitochondrial generation of phosphoenolpyruvate. The inhibitory effect of octanoate was reversed by ammonia. The results indicate that fatty acids and ammonia are potent regulatory factors of both the rate of glucose formation and the contribution of mitochondrial phosphenolpyruvate carboxykinase to gluconeogenesis in hepatocytes of the fasted rabbit.

0933 ACTION OF COBALT CHLORIDE ON THE BIOSYNTHESIS, DEGRADATION, AND UTILIZATION OF HEME IN FETAL RAT LIVER. (Eng.) Woods, J. S.; Carver, G. T. (Natl. Inst. Environmental Health Sciences, P.O. Box 12233, Research Triangle Park, NC 27709). *Drug Metab. Dispos.* 5(5):487-492; 1977.

The effects of cobalt chloride on heme biosynthesis and degradation and on the utilization of heme in the synthesis of various hemoproteins in fetal rat liver were investigated. $CoCl_2$ (50 mg/kg) administered to 18-day pregnant rats resulted in inhibition of the heme-biosynthetic pathway enzymes, δ-aminolevulinic acid (ALA) synthetase, and ferrochelatase, and increased the activity of microsomal heme oxygenase in fetal liver. Concomitantly, a 75-95% reduction in the rate of ^{3}H-ALA incorporation into fetal mitochondrial hemes was observed, and a 50% depletion of total microsomal heme levels occurred. Treatment of pregnant rats with $CoCl_2$ on the 18th day of gestation also resulted in a 35-40% reduction in the activities of cytochrome oxidase and aminopyrine demethylase measured in neonatal liver at 1 week after birth; deficiencies in both mitochondrial and microsomal hemoprotein function persisted for several weeks postnatally. Thus, $CoCl_2$ substantially alters hepatic heme metabolism in fetal liver. Utilization of agents such as $CoCl_2$ as pharmacological tools may permit a clearer understanding of the gestational role of heme in the perinatal development of hepatic hemoprotein function.

0934 LIPOGENESIS IN HEPATOCYTES OF GENETICALLY OBESE RATS. (Eng.) Bloxham, D. P.; Fitzsimons, J. T. R.; York, D. A. (Dept. Physiology and Biochemistry, Univ. Southampton, Southampton S09 3TU, England). *Horm. Metab. Res.* 9(4):304-309; 1977.

Lipogenesis from (U-^{14}C)lactate, (U-^{14}C)glucose, and tritiated water (^3H_2O) was investigated in hepatocytes obtained from both genetically obese rats and their lean littermates by the technique of nonrecirculating perfusion by gravity. Analysis of the incorporation of ^{14}C (microatoms of C/100 mg protein) from (U-^{14}C)lactate into various lipid fractions revealed a clear difference in the lipogenic capacity of hepatocytes from obese and lean rats on a standard chow diet. For hepatocytes from obese rats, the major product was triglyceride fatty acids (1.95 ± 0.11 versus 0.18 ± 0.01 microatoms of C/100 mg protein for lean hepatocytes, $p<0.001$), whereas for hepatocytes from lean rats the main product was glyceride-glycerol (3.48 ± 0.23 versus 0.61 ± 0.07 microatoms C/100 mg protein for obese hepatocytes, $p<0.001$) when these values were measured after 60 min of incubation with lactate. Sterol synthesis at this time was significantly higher ($p<0.001$) in hepatocytes from obese rats compared with lean rats (0.33 ± 0.04 versus 0.05 ± 0.01 microatoms of C/100 mg protein, resp.). There was virtually no difference in glucose incorporation into fatty acids in hepatocytes from either lean or obese rats, demonstrating that enhancement in hepatic fatty acid synthesis in the obese syndrome is related to increased activity of enzymes involved in lactate utilization rather than in enhanced conversion of glucose to lactate. Fatty acid synthesis increased in both lean and obese rats on a fat-free diet and fell markedly in both lean and obese rats when they were starved. Fatty acid synthesis in hepatocytes from obese rats was more resistant to starvation than in lean animals since fatty acid synthesis declined only to a rate of 0.23 microatoms C/100 mg protein/30 min in obese rats, whereas fatty acid synthesis was negligible in starved lean rats. When obese rats were changed from a chow diet to a fat free diet, lactate incorporation changed from being about equally divided between fatty acids and glyceride-glycerol to a 66% incorporation for fatty acids and a 19.3% incorporation for glyceride-glycerol. Following starvation in lean and obese rats, glyceride-glycerol represented the major point of lactate incorporation (54% for obese and 91% for lean). Studies involving the simultaneous incubation of hepatocytes with ^3H_2O and (U-^{14}C)-labeled substrates indicated that lactate is a major source of carbon for fatty acid synthesis at low concentrations and possibly the only source at high concentrations.

0935 PLASMA LIPOPROTEIN CHANGES IN EXPERIMENTAL CHOLESTASIS IN THE DOG. (Eng.) Danielsson, B.; Ekman, R.; Johansson, B. G.; Petersson, B. G. (Univ. Hosp., Lund, Sweden). *Clin. Chim. Acta* 80(1):157-170; 1977.

Using zonal ultracentrifugation, gel electrophoresis, and Sephadex gel chromatography, plasma lipoproteins were studied after 1 week of complete biliary obstruction in the dog. The common bile duct was ligated and transected in eight dogs, and two dogs were sham-operated. A considerable increase in low density lipoprotein (LDL) was found 1 week after operation, with a zonal ultracentrifugal pattern that was more complex than that found before operation. The lipid composition was characterized by an increase of phospholipids and a decrease of triglycerides in cholestatic LDL fractions. None of the fractions displayed the inverse cholesterol-cholesterol ester ratio characteristic for human LP-X. The apoprotein composition of cholestatic LDL was also markedly changed. Apoprotein A I, already present in the normal LDL_2 subclass, increased, and two apoproteins with apparent molecular weights of 35,000-40,000 appeared in considerable amounts. The amount of high density lipoprotein (HDL) was decreased during cholestasis without any appreciable changes in composition. The results support the hypothesis that lipoprotein changes in cholestasis are related to an abnormal transformation of HDL particles.

0936 STUDIES ON RAT LIVER PLASMA MEMBRANE: ALTERED PROTEIN AND PHOSPHOLIPID METABOLISM AFTER INJECTION OF D-GALACTOSAMINE. (Eng.) Bachmann, W.; Harms, E.; Hassels, B.; Henninger, H.; Reutter, W. (III Medizinische Abteilung des Krankenhauses Schwabing und Forschergruppe Diabetes, D-8000 Munchen, Kolner Platz 1, W. Germany). *Biochem. J.* 166(3):455-462; 1977.

The metabolism of protein and phospholipid in isolated rat liver plasma membranes was investigated 3 and 6 hr after the injection of D-galactosamine (375 mg/kg, i.p.) *in vivo*. During this time, all the biochemical and morphological alterations associated with hepatitis developed. After the injection of D-galactosamine the concentration of sphingomyelin in the plasma membrane decreased to below 60% of the control values. The activity of 5'-nucleotidase (EC3.1.3.5), which has been purified as a sphingomyelin-protein complex, decreased in the total homogenate as well as in the plasma-membrane fraction of livers of rats treated with galactosamine, to about 60% of the control values. Protein synthesis, as measured by the incorporation of [^{14}C]leucine into plasma membranes, was decreased to 45% of that of the controls. However, only small differences were observed in the amino acid composition of the plasma membrane after D-galactosamine treatment. The protein composition of the plasma membranes was determined by sodium dodecyl sulfate/polyacrylamide-gel electrophoresis. The results showed a change from low- to high-molecular weight proteins after the injection of galactosamine. These results demonstrate different metabolic processes of the plasma membrane altered during the induction of galactosamine hepatitis.

0937 THE ACTIVITY OF SILYBIN ON PHOSPHOLIPID METABOLISM OF NORMAL AND FATTY LIVER IN VIVO. (Eng.) Castigli, E.; Montanini, I.; Roberti, R.; Porcellati, G. (Inst. Biochemistry, Univ. Perugia, 06100 Perugia, Italy). *Pharmacol. Res. Commun.* 9(1):59-69; 1977.

The mechanism by which silybin corrects ethanol- and ethionine-induced changes in phospholipid metabolism was investigated in the livers of female Wistar rats treated with a single dose of ethanol (0.6 g/100 g, p.o.) or with DL-ethionine (2 ml/150 g at 1, 8, 24, 32, and 48 hr, s.c.). Ethanol significantly increased the incorporation rate of labeled orthophosphate (10 μCi, i.p.) into liver phosphatidylcholine (Ptd-Cho, 14.7 ± 1.62 counts per minute [cpm]/μg phospholipid [P] in control experiments versus 20.9 ± 2.14 cpm/μg P, $p<0.001$), but did not affect orthophosphate incorporation into liver phosphatidylethanolamine (Ptd-Etn). Ethionine treatment inhibited the incorporation of labeled phosphate into both Ptd-Cho (16.1 ± 2.11 cpm/μg P versus 6.7 ± 0.86 cpm/mg P, $p<0.001$) and Ptd-Etn (11.2 ± 1.32 cpm/μg P versus 5.4 ± 0.61 cpm/μg P, $p<0.001$). The administration of silybin hemisuccinate sodium salt (150.6 mg/kg/day, i.v., corresponding to 100 mg/kg/day silybin base) for 5 days before the administration of ethionine or ethanol resulted in a Ptd-Cho level in the ethanol-treated rats nearly as low as the control level (15.2 ± 2.16 cpm/μg P). This result was probably due to the fact that the administration of silybin alone slightly decreased the rate of phosphate incorporation into lipid. Silybin administration significantly increased the rate of labeled phosphate into both Ptd-Cho (10.1 ± 1.12 cpm/μg P) and Ptd-Etn (7.5 ± 0.89 cpm/μg P) in the ethionine-treated rats, although not to control levels. In the untreated rat liver, silybin treatment did not inhibit phospholipid synthesis from choline, ethanolamine, or phosphate. The results suggest that the effect of silybin on the normal liver is different from that in ethanol- or ethionine-induced fatty liver, which is probably a result of a change in membrane structure in the fatty liver.

0938 THE INTERACTION OF HEPATOCYTE PLASMA MEMBRANES WITH AN AZIDE DERIVATIVE OF PROCAINE. (Eng.) Levy, D.; Glover, E.; Cheng, S. (Univ. Southern California, Sch. Medicine, Los Angeles, CA 90033). *Biochim. Biophys. Acta* 469(2):194-201; 1977.

The binding sites of procaine were characterized in rat liver plasma membranes. A photoreactive derivative of procaine, *p*-azidobenzoyldiethylaminoethanol hydrochloride, was synthesized and used as a site-directed probe to label hepatocyte plasma membranes. The procaine derivative was shown to have membrane binding and Ca^{2+} displacement characteristics quite similar to that of procaine. Photolysis of the derivative in the presence of hepatocyte plasma membranes resulted in the covalent incorporation of the probe into both the protein and lipid fractions. Analysis of the labeled membranes by sodium dodecyl sulfate-polyacrylamide gel electrophoresis indicated that one membrane protein was significantly labeled with a molecular weight of 21,400 in addition to membrane lipids. Both binding and labeling could be inhibited in the presence of an excess of procaine. The labeled membrane components may be involved in the binding of Ca^{2+} to the membrane system.

0939 THE METABOLISM OF CHYLOMICRON REMNANT BY ISOLATED PERFUSED RAT LIVER. (Eng.) Cooper, A. D. (Stanford Univ. Sch. Medicine, Stanford, CA 94305). *Biochim. Biophys. Acta* 488(3):464-474; 1977.

The isolated perfused rat liver was used to study the hepatic metabolism of chylomicron remnants and to assess the hypothesis that they are the lipoprotein particles of dietary origin that can exert physiologic regulation of hepatic cholesterol synthesis. When whole chylomicrons containing radiolabeled lipids were added to the perfusate of an isolated liver, virtually no cholesterol ester or triacylglycerol was removed during the first hour, while a small amount of free cholesterol disappeared. After 3 hr, 40% of the cholesterol ester was removed by the liver. When chylomicron remnants, prepared by incubation of chylomicrons with postheparin plasma and containing the same amount of cholesterol, were added to the perfusate, 76 ± 7% of the cholesterol ester was removed in the first hour. Moreover, free cholesterol and triacylcerol disappeared from the perfusate at the same rate as the cholesterol ester, and, during the early phase of the perfusion, the total perfusate cholesterol content declined by the same amount as the radioactive cholesterol content. These results suggest a specific removal of the intact lipoprotein particle. Of the cholesterol ester removed, 42% was hydrolyzed to free cholesterol after 3 hr. When whole chylomicrons, containing the same amount of cholesterol, were injected into rats *in vivo*, 71 ± 4% of the cholesterol ester was removed by the liver in 3 hr, and 53% of this was hydrolyzed. The activity of 3-hydroxy-3-methylglutaryl-coenzyme A reductase, the rate-limiting enzyme of cholesterol synthesis, increased during liver perfusion with plasma-free or chylomicron-containing perfusate while addition of chylomicron remnants to the perfusate significantly diminished the effect. It is concluded that the chylomicron remnant is the lipoprotein of alimentary origin that regulates hepatic cholesterol synthesis, and that its metabolism by isolated liver appears to reflect the hepatic component of chylomicron metabolism *in vivo*.

0940 BILE CANALICULAR MEMBRANE PATHOLOGY IN CYTOCHALASIN B-INDUCED CHOLESTASIS. (Eng.) Oda, M.; Phillips, M. J. (Dept. Pathology, Univ. Toronto, 100 College St., Toronto, Ontario, Canada). *Lab. Invest.* 37(4):350-356; 1977.

The mechanism of cytochalasin B-induced intrahepatic cholestasis was examined in both isolated Wistar rat hepatocytes and *in vivo* infused liver using electron cytochemical techniques. Markers were used for three canalicular membrane components, namely ruthenium red for the glycoprotein-rich surface coat, the Mg^{2+}-ATPase reaction as an example of a membrane-bound protein, and uranyl acetate *en bloc* and ruthenium red staining for the canalicular membrane-associated microfilaments. In rat liver infused *in vivo* with cytochalasin B, reduction in bile flow correlated with bile canalicular dilation, loss of the ruthenium red-positive surface coat from the canalicular membrane, and loss of demonstrable Mg^{2+}-ATPase activity. In addition, structural alterations in microfilaments with widening of the ectoplasmic zone were noted. In isolated liver cells, identical changes were found. Bile canaliculi isolated from the *in vivo* cytochalasin B-infused rat liver lacked their normal investment of microfilaments. Detachment of the filaments from the bile canalicular membrane may be involved in the mechanism of cytochalasin B-induced cholestasis.

0941 THE EFFECT OF DIETARY PROTEIN DEPRIVATION ON PROTEIN SYNTHESIS IN THE ISOLATED LIVER PARENCHYMAL CELL.

(Eng.) Grant, A. G.; Hoffenberg, R. (St. George's Hosp. Medical Sch., Cranmer Terrace, Tooting, London SW17 0RE, England). *Br. J. Nutr.* 38(2):255-260; 1977.

Protein synthesis was compared in hepatic parenchymal cells from normal rats and from rats that had been deprived of dietary protein for 3 weeks. The cells from protein-deprived rats were two-thirds the diameter of those derived from livers of normal animals, and they consumed oxygen at a rate of 16.2 ± 2.7 µl/hr/10^6 viable cells, half the normal value. Albumin and transferrin were synthesized at rates of 0.94 ± 0.12 and 0.60 ± 0.07 µg/hr/10^6 viable cells, resp., and urea at a rate of 0.77 ± 0.12 µg/hr/10^6 cells from protein-deprived rats, which represents a 25-50% decrease in the rates of synthesis measured in cells isolated from normal livers. The 50% decrease in O_2 consumption in cells from protein-deprived rats is compatible with their smaller diameter and volume and suggests a decrease in either the size or number of mitochondria in each cell. The maintenance of cell viability and the inability of essential and nonessential amino acids to increase protein or urea synthesis in these cells suggests that the overall adaptation to protein deprivation is a general reduction in cell size rather than the withdrawal of cells from protein synthesis.

0942 CATABOLISM OF α-FETOPROTEIN IN CARBON TETRACHLORIDE-INJURED RATS.

(Eng.) Watanabe, A.; Miyazaki, M. (Okayama Univ. Medical Sch., Okayama 700, Japan). *Acta Hepatogastroenterol.* 24(4):238-240; 1977.

The rate of alpha-fetoprotein (AFP) catabolism was determined in male Sprague-Dawley rats with carbon tetrachloride-induced liver injury and compared with that in normal rats. The rate of AFP catabolism in CCl_4-treated rats was estimated to be essentially the same as that found in control adult and young rats. The blockade of the reticuloendothelial system by carbon particles resulted in slightly shorter values for AFP half-life. The amount of AFP synthesized per day in CCl_4-treated rats was calculated to be nearly 10 times that in controls. Thus, the elevation of serum AFP concentrations in CCl_4-treated rats is derived from increased AFP synthesis by the injured liver.

0943 THE INFLUENCE OF INCREASED HEPATIC SEQUESTRATION AFTER SPLENECTOMY ON THE SURVIVAL AND OSMOTIC FRAGILITY OF RED CELLS IN RATS, WITH REFERENCE TO PROTEIN LEVELS IN DIETS.

(Eng.) Hisaoka, F.; Shiraki, K.; Sagawa, S. (Sch. Medicine, Tokushima Univ., 3 Kuramotocho, 770 Tokushima, Japan). *J. Nutr. Sci. Vitaminol.* 23(3): 237-247; 1977.

The sequestration of RBC in rats by the liver following splenectomy was studied using an isologous ^{51}Cr-labeled population of either normal or *N*-ethylmaleimide (NEM) treated RBC. The spleen sequestered the damaged RBC selectively, while the liver compensated and overshot the sequestration for spleen after splenectomy. The sequestering response in liver increased gradually, reaching a maximum level 8 weeks after splenectomy and then declined toward the control level. These compensatory responses in liver were not observed in rats fed a low-protein diet, which indicated that the proliferative response imposed on liver by an extra work after splenectomy was not stimulated in the rats fed a low-protein diet. Splenectomy prolonged RBC survival and reduced the osmotic fragility of normal RBC, but the compensatory increase in sequestration of damaged RBC in the liver did not alter the survival and osmotic fragility of normal RBC of the rat. These findings indicate that the increased sequestration of reticuloendothelial cells in the liver is basically reparative and that it is impossible to compensate for the absence of the spleen because of an inability to duplicate certain anatomic features peculiar to the spleen.

0944 EFFECT OF GLUCOCORTICOID ON PROSTAGLANDIN PRODUCTION DURING SIMULATED SHOCK CONDITIONS IN THE PERFUSED CAT LIVER.

(Eng.) Carlson, R. P.; Flynn, J. T.; Lefer, A. M. (Jefferson Medical Coll., Philadelphia, PA 19107). *Biochem. Pharmacol.* 26(16):1463-1468; 1977.

The production of prostaglandins E_2 and $F_{2\alpha}$ by isolated perfused cat livers was quantitated during separate simulated shock conditions (i.e., ischemia, acidosis, and hypoxia). Control livers showed little change in perfusate prostaglandin concentrations over a 150-min perfusion period. Neither ischemia nor acidosis produced significant increases in prostaglandin concentrations in the perfusate after 150 min of perfusion. Hypoxia resulted in a 4.5-fold increase in PGE_2 and a 3.5-fold increase in $PGF_{2\alpha}$ concentrations during this same period. Lactic acid dehydrogenase and cathepsin D activities were also elevated in the perfusate during hypoxia. The addition of methylprednisolone (10^{-3} M) to the perfusate significantly retarded the release of PGE_2, $PGF_{2\alpha}$, and cathepsin D into the perfusate during severe hypoxia, without significantly altering the increase in lactic acid dehydrogenase activity. The action of methylprednisolone on prostaglandin and lysosomal enzyme release in hypoxic livers may be the result of a membrane-stabilizing action of the glucocorticoid. One possible mechanism for the inhibition by glucocorticoids of the increased prostaglandin production during hypoxia is that endogenous arachidonic acid is stabilized within the cell membrane phospholipids, thus, less substrate is available for utilization by the prostaglandin synthetase system.

0945 THE EFFECT OF ANOXIA ON NITROGEN METABOLISM IN THE ISOLATED PERFUSED RAT LIVER. (Eng.)

Parrilla, R.; Goodman, M. N.; Toews, C. J. (Dept. Metabolism, Inst. G. Maranon, C.S.I.C., Madrid, Spain). *Pfluegers Arch.* 369(2):167-175; 1977.

The roles of different substrates and of anoxia in hepatic alanine metabolism were studied to elucidate the metabolic situations that would cause a reversal of the normal alanine flux from the extra- to the intra-cellular hepatic spaces. The total nitrogen balance of the liver was accounted for by proteolysis; production of alanine, glutamine, urea, and ammonia; and uptake of pyruvate, alanine, or glutamine uptake. The rate of alanine production was a function of the hepatic alanine concentration when it was not added as a substrate. Anoxia increased hepatic alanine production, largely due to an increased rate of proteolysis (chiefly of glutamate). However, a decrease in the glutamate level in the liver could not account for the increased alanine, thus suggesting intramitochondrial synthesis of glutamate that is then transferred to the cytosol. The mitochondrial $(NAD^+)/(NADH)$ ratio calculated from the glutamate or β-hydroxybutyrate dehydrogenase reactions was the same in both control and hypoxic livers, suggesting that the two enzymes are in equilibrium with the mitochondrial nicotinamide nucleotide pool. Anoxia had marked effects on nitrogen balance in the liver. When pyruvate was the substrate, the total hepatic nitrogen production increased, with most of the increase accounted for by alanine production. It is concluded that pyruvate availability is the critical factor in determining the rate of alanine production under all conditions studied and that increased proteolysis is the significant factor for increased hepatic nitrogen production during anoxia.

0946 DIFFERENTIAL ACTION OF PROGESTERONES ON HEPATIC MICROSOMAL ACTIVITIES IN THE RAT.

(Eng.) Feuer, G.; Kardish, R.; Farkas, R. (Banting Inst., Toronto, Ontario M5G 1L5, Canada). *Biochem. Pharmacol.* 26(16):1495-1499; 1977.

To test the hypothesis that changes in normal steroid balance could influence the metabolism of drugs and the pattern of liver response, the effect of the administration of reduced derivatives of progesterone (5α-pregnane-3β-ol-20-one, 5β-pregnane-3α-ol-20-one, 5α-pregnane-3β,20β-diol, and 5β-pregnane-3α,20α-diol) on the microsomal hydroxylation of selected drugs and of progesterone was measured in rats. The s.c. administration of these steroids in seven daily doses (20 mg/kg) significantly reduced the activities of aminopyrine *N*-demethylase, coumarin 3-hydroxylase, and glucose 6-phosphatase in hepatic microsomes. These steroids slightly raised inosine diphosphatase activity. 16α-Hydroxyprogesterone and pregnenolone-16α-carbonitrile significantly increased drug metabolism and slightly elevated glucose 6-phosphatase. The contrasting action of the different progesterone derivatives was associated with changes in microsomal phospholipid synthesis. Pregnanolone and pregnanediol significantly decreased the *de novo* incorporation of [^{14}C-methyl]-L-methionine into microsomal phospholipids, mainly manifesting in phosphatidylcholine, phosphatidylethanolamine, and lysophosphatidylcholine fractions; reduced the activity of S-adenosyl-L-methionine:microsomal-phosphatidylethanolamine methyl transferase; and caused a reduction of total microsomal phosphatidylcholine:phosphatidylethanolamine ratio. In contrast, 16α-hydroxy-progesterone and pregnenolone-16α-carbonitrile increased the *de novo* synthesis of microsomal phospholipids, methyl transferase activity, and the ratio of total microsomal phosphatidylcholine: phosphatidylethanolamine. Treatment with reduced progesterone derivatives diminished microsomal progesterone hydroxylation in the 16α- and 6β-position and raised progesterone Δ^4-5α-dehydrogenase activity measured *in vitro*. 16α-Hydroxyprogesterone and pregnenolone-16α-carbonitrile elevated progesterone hydroxylation. Considering these opposite effects, it can be postulated that, in the rat, the induction of drug metabolizing activity of the hepatic endoplasmic reticulum might be controlled by a balance displayed in the synthesis and metabolism of various progesterone derivatives.

0947 BIOTRANSFORMATION OF DRUGS AND THEIR INTERACTION WITH BARBITURATES. (Ger.)

Remmer, H. (Institut fur Toxikologie, Universitat Tubingen, Wilhelmstr. 56, 7400 Tubingen, W. Germany). *Z. Gastroenterol.* 15(6):362-372; 1977.

Studies on drug metabolism by liver enzymes are reviewed. The formation of oxidized compounds is the first step of the enzymatic biotransformation of drugs in the liver, which gives rise to radical intermediates that may elicit toxic action if not removed immediately by consecutive enzymatic reactions. The problem of liver enzyme induction by prescription drugs is generally overemphasized; the therapeutic doses used are normally too low to evoke increased enzyme production. Only few therapeutic drugs are known to act as enzyme inducers, either because they have to be used in high doses (e.g., rifampicin) or because of their ability to accumulate during treatment (e.g., phenobarbital, phenytoin). The inducing action is dependent on the drug concentration in the liver and inversely related to the rate of the breakdown of the drug. Inhibition of drug metabolism seems to be more important in therapy: as exogenous and endogenous liposoluble compounds compete for the binding sites of the oxidizing and conjugating enzymes, the release of a drug from the enzyme site depends on the concentration and affinity of the displacing agent. Only drugs administered in a high dose range are able to inhibit the metabolism of another drug administered in a lower dose. Such competitive inhibition of metabolism leads to an increase in the therapeutic effect, and possibly also the toxic effect, of the drug whose metabolism is inhibited. If a drug produces the same therapeutic effect and has a similar therapeutic index as another drug, but is administered in a lower dose, an interaction with the second drug is very unlikely. Such combinations of drugs should be preferably prescribed to prevent interactions.

0948 EFFECT OF EXPERIMENTAL HEPATIC INJURY ON IN VITRO DRUG-METABOLIZING ENZYME ACTIVITIES IN THE RAT.

(Eng.) Willson, R. A.; Hart, F. E. (Harborview Medical Center, 325 9th Ave., Seattle, WA 98104). *Gastroenterology* 73(4):691-696; 1977.

The relationship between *in vitro* drug metabolism, liver necrosis, and liver function test results was studied in male Sprague-Dawley rats with acetaminophen-induced liver injury. Hepatic necrosis was induced in phenobarbital-pretreated rats by the i.p. administration of an acetaminophen-dimethyl sulfoxide mixture (0.3-1.5 g/kg). At lower doses, cytochrome P-450 concentration and the specific activities of aminopyrine demethylase and bilirubin glucuronyl transferase increased, whereas aniline hydroxylase activity was mildly decreased. In contrast, at higher doses, cytochrome P-450 concentration and the specific activities of all of the enzymes were decreased significantly ($p<0.01$), as compared with control rats. The diminished activities, however, were generally modest, not uniform for all enzymes assayed, and correlated poorly with histological necrosis and routine laboratory tests. When necrosis was severe, a prominent peak was detected at 420 nm, and this was associated with a more consequential decrease in all of the enzyme activities. When the total *in vitro* hepatic drug metabolizing enzyme capacity was calculated, only the cytochrome P-450 content and aminopyrine demethylase activity were significantly decreased at the 1.5-g/kg dose. It is concluded that, in acute liver disease, changes in the hepatic *in vitro* drug metabolizing enzyme capacity may not be closely related to cellular necrosis, *per se*, and the degree of change in enzyme activities varies from one enzyme system to another. These findings may explain, in part, the often inconsistent alterations in the disposition and elimination of drugs described in associated liver diseases.

0949 INTERFERENCE OF CCl_4 METABOLITES WITH SUBCELLULAR STRUCTURES.

(Eng.) Dianzani, M. U.; Gabriel, L.; Gravela, E.; Paradisi, L. (Istituto di Patologia Generale, Corso Raffaello 30, Torino, Italy). *Panminerva Med.* 18(9/10):310-319; 1976.

The effect of aldehydes and ketoaldehydes on the amino acid incorporating activity of the postmitochondrial supernatant from rat liver was studied to determine whether these substances, which are produced during the peroxidation of unsaturated fatty acids, could be involved in carbon tetrachloride-induced liver injury. *In vitro* protein synthesis was inhibited by 10 mM malonyldialdehyde, 5 mM 2-ketopentanal, 1 mM 4-hydroxypentenal, and 0.25 mM malealdehyde. Thiol compounds protected against 4-hydroxypentenal- and malealdehyde-induced inhibition of protein synthesis, indicating that the inhibition is dependent upon a blocking of sulfhydryl groups. CCl_4 (50 mM) inhibited polyuridine-directed phenylalanine incorporation in the postmitochondrial supernatant to 54% of the control level. The degree of inhibition was not affected by NADPH, and antioxidants did not protect against the inhibi- 0.1 mM $CBrCl_3$. This inhibition was intensified by NADPH. Polyuridine-directed polyphenylalanine synthesis was more severely impaired than was endogenous messenger RNA-dependent synthesis.

0950 ADVERSE EFFECTS OF CHLORPROMAZINE METABOLITES ON ISOLATED HEPATOCYTES.

(Eng.) Abernathy, C. O.; Lukacs, L.; Zimmerman, H. J. (Veterans Admin. Hosp., 50 Irving St., N.W., Washington, DC 20422). *Proc. Soc. Exp. Biol. Med.* 155(4):474-478; 1977.

Chlorpromazine (CPZ) and several of its metabolites were tested for *in vitro* cytotoxicity, as measured by the efflux of aspartate aminotransferase to the surrounding medium, toward isolated rat hepatocytes. Exposure of liver cells to CPZ (9 x 10^{-5} M) led to enzyme leakage. The demethylated metabolites, mono- and didesmethyl-CPZ, were three and six times, resp., more potent than CPZ. Hydroxylation of the tricyclic ring at the 7 or 8 position gave rise to compounds that were slightly less active than the parent compound, while oxidation of the sulfur atom resulted in inactive analogs. The presence of calcium in the medium had no apparent effect on the response of the hepatocytes to CPZ. The results are consistent with the hypothesis that certain drugs, which cause jaundice in a small percentage of patients, possess a slight intrinsic toxicity.

0951 COMPARATIVE TOXICITIES OF ENFLURANE, FLUROXENE AND NITROUS OXIDE AT SUBANAESTHETIC CONCENTRATIONS IN LABORATORY ANIMALS.

(Eng.) Stevens, W. C.; Eger, E. I., II; White, A.; Biava, C. G.; Gibbons, R. D.; Shargel, R. (Univ. California Medical Center, 436S, San Francisco, CA 94143). *Can. Anaesth. Soc. J.* 24(4):479-490; 1977.

The toxicities of subanesthetic concentrations of fluroxene, enflurane, and nitrous oxide were compared in mice, rats, and guinea pigs, which were all young and in an active growth phase. Fluroxene (>0.001% of air delivered in a closed chamber) produced a greater mortality and decrement in weight gain than did enflurane and nitrous oxide, despite the administration of far lower concentrations. All species that received 0.2% enflurane gained less weight than controls. Reduction of enflurane to 0.07% reduced the detrimental effect on all species. Five male mice receiving 0.2% enflurane died by day 5, and by day 17, nine male and six female mice receiving 0.07% died. No rats receiving enflurane died. One male and two female guinea pigs that received 0.07% enflurane died. Of the controls, only one guinea pig died. Mice treated with 20% nitrous oxide gained more weight than controls. Experimental and control rats had similar weight gain, but experimental guinea pigs gained less weight than controls. Of the experimental animals, only two guinea pigs died, whereas two mice and one guinea pig in the control group died. Control female mice for the 0.01% fluroxene group were significantly heavier than the experimental mice before anesthesia administration, and this difference increased significantly at 4 days. Experimental male mice receiving 0.003% fluroxene were significantly heavier than the control mice before anesthesia, but this difference was reversed in only 5 days. Fluroxene was lethal to mice at 0.003%, and was poorly tolerated by any species for even brief periods at 0.01%. Nitrous oxide (0.1 minimum alveolar concentration) resulted in an increased incidence of focal inflammatory liver changes in mice (occurring in 5/15 controls and 34/42 experimental animals). Renal tubule calcification occurred in 2 of 7 controls and 5 of 10 experimental guinea pigs. Histologic changes produced by the other two agents were inconsistent. This study confirms the toxicity of fluoroxene in laboratory animals.

0952 THE ROLE OF BILIARY EXCRETION IN THE HEPATOTOXICITY OF FUROSEMIDE IN THE MOUSE.

(Eng.) Spitznagle, L. A.; Wirth, P. J.; Boobis, S. W.; Thorgeirsson, S. S.; Nelson, W. L. (Dept. Pharmaceutical Sciences, Univ. Washington, Seattle, WA 98195). *Toxicol. Appl. Pharmacol.* 39(2):283-294; 1977.

The distribution of furosemide in the whole body and its binding to plasma proteins were studied in adult male Swiss-Webster mice or Swiss albino mice to elucidate the importance of biliary excretion in the hepatotoxicity of furosemide. Whole-body autoradiography (after administration, i.v. or i.p., of ^{35}S-furosemide, 150-300 mg/kg) showed that large amounts of furosemide and its metabolites accumulated in the gastrointestinal tract and that the excretory process through the biliary tract proceeded by a saturable, dose-dependent mechanism. More than 30% of the furosemide was excreted in the bile after doses of 50 and 100 mg/kg, but considerably less was excreted at higher doses. BSP administration decreased the biliary excretion and increased hepatic necrosis of furosemide (necrosis index was 2.63 when BSP was given with furosemide as compared to 1.07 with furosemide alone). However, equilibration of BSP with serum did not affect the binding of furosemide (5-500 μg/ml) to serum proteins. Two classes of binding sites for furosemide, differing in their association constants (KA), were found in the serum: K_A=7.5 x 10^4 and 1.1 x 10^3. Total metabolism of furosemide and its covalent binding to liver proteins increased with increasing doses of the drug and correlated with corresponding increases in hepatotoxicity. It is concluded that biliary excretion is of considerable importance in the elimination of potentially hepatotoxic doses of furosemide in the mouse and that blocking this pathway (saturation with furosemide or BSP) leads to the observed hepatic necrosis.

0953 α-NAPHTHYLISOTHIOCYANATE (ANIT) HEPATOTOXICITY AND IRREVERSIBLE BINDING TO RAT LIVER MICROSOMES.

(Eng.) El-Hawari, A. M.; Plaa, G. L. (Faculte de Medecine, Universite de Montreal, Montreal, Quebec, Canada). *Biochem. Pharmacol.* 26(20):1857-1866; 1977.

Experiments were carried out to determine whether the irreversible binding of α-naphthylisothiocyanate (ANIT) to hepatic macromolecules is related to its hepatotoxic effect. The binding of a chemically reactive ANIT-derived product to rat liver microsomes was examined *in vitro*. When [^{3}H]ANIT or [^{14}C]ANIT was incubated with rat liver microsomes, radioactivity was bound irreversibly to proteins. This binding occurred in the absence (nonenzymic) and, to greater extent, in the presence (enzymic) of NADPH and oxygen. Enzymic binding was inhibited by carbon monoxide, β-diethylaminoethyl diphenylpropylacetate (SKF 525-A), and piperonyl butoxide, indicating that a cytochrome P-450-dependent, mixed-function oxidase mediated the binding. The enzymic binding was reduced by incubation with glutathione and other thiol-containing compounds, while incubation with β-naphthylisothiocyanate or phenylisothiocyanate inhibited both the enzymic and nonenzymic binding. Pretreatment of rats with phenobarbital or 3-methylcholanthrene enhanced ANIT toxicity *in vivo* and markedly increased the irreversible binding *in vitro*. Piperonyl butoxide, SKF 525-A, disulfiram, and cobaltous chloride reduced ANIT toxicity and its binding to microsomes *in vitro*. However, cycloheximide, which abolished ANIT toxicity *in vivo*, failed to affect the binding. Furthermore, 16-α-pregnenolone carbonitrile reduced ANIT toxicity *in vivo* but increased its enzymic binding. The results demonstrate an inconsistent correlation between toxicity of ANIT *in vivo* and its binding to microsomal proteins *in vitro* and indicate that binding *in vitro* in itself is not a valid index of ANIT-induced hyperbilirubinemia. Limited studies *in vivo* in which the irreversible binding to liver proteins was examined after p.o. ANIT administration indicated that the extent of binding after different pretreatments also did not parallel ANIT toxicity. These data cast doubt on the role of such binding in the pathogenesis of ANIT-induced cholestasis.

0954 MICROSOMAL HEXOBARBITAL METABOLIZING ENZYMES IN REGENERATING CHOLESTATIC RAT LIVER.

(Eng.) Ahonen, J.; Aronsen, K. F. (Helsinki Univ. Central Hosp., Helsinki, Finland). *Eur. Surg. Res.* 9(4):264-269; 1977.

Microsomal changes were studied in regenerating cholestatic rat liver by measuring hexobarbital metabolizing capacity (HMC) *in vitro*. Total extrahepatic biliary obstruction was induced in male Sprague-Dawley rats by common duct ligation, and 3 days later a 70% hepatectomy was carried out. In sham-operated control rats, hepatectomy resulted in a clear reduction in HMC. On day 7 after hepatectomy, an increase in HMC was observed. In the duct-ligated group, the initial value of HMC was reduced as compared with that in the sham-operated animals. Liver resection caused a further reduction in the activity, but the HMC activity started to increase at the same time as that in the sham-operated group. The similarity of the pattern of microsomal regeneration in duct-ligated and sham-operated rats indicates that cholestasis per se does not interfere with the development of the microsomal hexobarbital metabolizing enzyme system during regeneration.

0955 INDUCTION OF LIVER LYSOSOMAL ENZYMES DURING THE AUTOPHAGIC PHASE FOLLOWING PHENOBARBITAL TREATMENT OF RAT. (Eng.) Glaumann, H.; Arborgh, B.; Lindeborg, T. (Karolinska Institutet, Box 6401, S-113 82 Stockholm, Sweden). *Virchows Arch.* [*Cell Pathol.*] 23(1):17-28; 1977.

To find a possible biochemical correlation to the increased occurrence of autophagy observed after phenobarbital treatment, hydrolytic (lysosomal) enzymes were analyzed in rats during the autophagic phase. Male rats received phenobarbital (8 mg/100 g) i.p. either as a single dose or once daily for 7 days. The effects of treatment on the lysosomal hydrolases, acid phosphatase, cathepsin D, and aryl sulfatase were analyzed at different intervals ranging from 1 to 15 days after seven injections, and from 1 to 48 hr after a single injection. In both cases, microsomal protein and NADPH-cytochrome c reductase were measured to ensure proper induction. After a single injection, a slight decrease in hydrolytic activities was observed. Repeated administration of phenobarbital gave rise to a marked decrease of lysosomal enzyme activities 1 day after cessation of treatment. This decrease was followed by a continuous increase in activity up to days 3 and 4. One or 2 weeks after treatment, enzyme activities declined to control values. The increase in activity of lysosomal hydrolytic enzymes was correlated with the onset of induced autophagy of endoplasmic reticulum membranes described as occurring in liver upon cessation of phenobarbital exposure. It is concluded that phenobarbital treatment *per se* decreases lysosomal enzyme activities, whereas the induced autophagy following cessation of exposure is associated with enhanced levels of lysosomal hydrolases in rat liver.

0956 CYCLIC EXCRETION OF HEPATITIS A VIRUS IN EXPERIMENTALLY INFECTED CHIMPANZEES: BIOPHYSICAL CHARACTERIZATION OF THE ASSOCIATED HAV PARTICLES. (Eng.) Bradley, D. W.; Gravelle, C. R.; Cook, E. H.; Fields, R. M.; Maynard, J. E. (Center for Disease Control, 4402 North Seventh St., Phoenix, AZ 85014). *J. Med. Virol.* 1(2): 133-138; 1977.

The excretion pattern of hepatitis A virus (HAV) particles was studied in two experimentally infected chimpanzees to examine its relation to SGPT activity. The two chimpanzees were infected with Phoenix antigen of HAV. Radioimmunoassay of daily 10% stool suspensions showed a cyclic excretion of virus particles on days 9-11, 14-15, and 20-21 post-inoculation and a maximum in SGPT activity on days 30-31. Immune electron microscopy of stool filtrates showed the presence of predominantly empty (electron-lucent) HAV particles on day 10, but predominantly complete (electron-dense) HAV particles on day 14, suggesting that virus particles with different biophysical properties might be found in stools collected at different times after inoculation of the animal. Isopycnic banding in CsCl gradients of stool suspensions (17%) prepared from 9-11, 14-15, and 17, 19, and 21 day stool pools showed multiple buoyant densities for the associated HAV particles. Hollow HAV particles found in the 9-11 day pool banded primarily at a buoyant density of 1.30 g/cm^3. HAV particles in the 14-15 day pool and in the 17, 19, and 21 day pool banded bimodally with antigen peaks at buoyant densities of 1.29 and 1.33 g/cm^3 (14-15 day) and 1.33 and 1.40 g/cm^3 (17, 19, and 32 day), resp. Replication of HAV in experimentally infected chimpanzees is accompanied by the cyclic excretion of HAV particles that exhibit varying buoyant densities in CsCl gradients.

0957 CHRONIC BILE DUCT CANNULATION OF RHESUS MACAQUES (Macaca mulatta) WITHOUT CAUSING BILIARY FISTULAS. (Eng.) Cloyd, G. G.; Hiles, R. A.; Caudill, D. (Miami Valley Lab., Procter & Gamble Co., Cincinnati, OH 45247). *Am. J. Vet. Res.* 38(10):1607-1610; 1977.

SECRETION AND METABOLISM

Intestine

1007 EFFECT OF LUMENAL CONTENTS ON COLONIC CELL REPLACEMENT. (Eng.) Stragand, J. J.; Hagemann, R. F. (Allegheny General Hosp., Pittsburgh, PA 15212). *Am. J. Physiol.* 233(3): E208-E211; 1977.

The role of physical versus nutritional stimulation in the response of colonic cell proliferation to fasting and refeeding (marked depression and transient stimulation, resp.) was evaluated in HA/ICR mice via a nondestructive colonic ligation procedure. The mice were fasted for 24 hr to remove food from the intestinal lumen. The colon was then ligated at the ascending region, 2 cm from the ileocecal junction. The fast was continued for an additional 48 hr. The mice were then refed for 8 hr, injected with tritiated thymidine, and sacrificed. The side of the colon proximal to the ligation and in contact with the food showed a dramatic response to refeeding (425 ± 75% greater cell renewal than that in sham-operated, nonfasting controls), whereas the side distal to the ligation remained depressed at the fasting level. The magnitude of ligation-induced colonic distention was such that the diameter of the proximal region of fasted and ligated animals was 1.5 times that of the controls and 2.6 times that of the distal region. The distal region of a fasted and ligated animal did not differ significantly from that of a fasted-only animal. The differences between the proximal and distal regions were similar in magnitude to that seen within 8 hr after refeeding; the colonic diameter was increased 2.1 times from the fasting level. Ligation produced a marked increase in the proliferative activity of the proximal colon within 48 hr, and the hyperproliferation occurred despite continued fasting stress. The region distal to the ligation remained depressed throughout. The results suggest that physical stimulation by lumenal factors is in part required to initiate the colonic hyperplasia seen after refeeding. Physical stimulation may be manifested through the lumenal distention produced by newly ingested food.

1008 DIETARY INFLUENCE ON COLONIC CELL RENEWAL.

(Eng.) Stragand, J. J.; Hagemann, R. F. (Allegheny General Hosp., 320 East North Ave., Pittsburgh, PA 15212). *Am. J. Clin. Nutr.* 30(6): 918-923; 1977.

The role of specific dietary components in the control of the response seen in the colon after starvation and refeeding and in normal colonic cell renewal was investigated in mice. The colonic refeeding response was dependent upon the presence of sugar, amino acids, and minerals (in the form of salts) in the refed diet. In the nonfasting animal, normal colonic cell renewal also required dietary minerals. The absence of minerals in a maintenance diet resulted in a marked hypoproliferative state that was reversed by reintroducing the mineral component of the diet. The depressed proliferative rate observed with a salt-free diet was not the result of a caloric depletion as demonstrated by the maintenance of body weight throughout the experimental period. These findings suggest a potential role for specific dietary components in the control of the colonic cell proliferation and in maintenance of the steady state cell renewal system, and represent a tool by which intestinal proliferative activity may be manipulated.

1009 ILEAL MUCOSAL CYCLIC AMP AND Cl SECRETION: SEROSAL VS. MUCOSAL ADDITION OF CHOLERA TOXIN.

(Eng.) Sheerin, H. E.; Field, M. (Harvard Medical Sch., Boston, MA 02215). *Am. J. Physiol.* 232(2):E210-E215; 1977.

The effect of adding cholera toxin to the mucosal (CT_m) and serosal (CT_s) sides of isolated rabbit small intestine on cyclic (c) AMP concentration and ion transport was studied to elucidate the relationship between cAMP and secretion. Preparations of 2-cm segments of the distal ileum of New Zealand white male rabbits, stripped of muscle, were mounted in chambers containing bicarbonate-Ringer solution (pH 7.4), glucose, and mannitol (10 µmol/ml each). The transmural potential difference, short circuit current (SCC), and electrical resistance were determined. Cholera toxin (50 µg) was added to either the mucosal or serosal reservoirs, and ion flux was measured with tracer doses of ^{22}Na and ^{36}Cl. The concentration of cAMP in the tissue was measured in a protein-kinase binding assay by adding theophylline (5 µmol/min) to the reservoirs 180 and 280 min after toxin addition; after 10 min, the tissues were placed in cold 5% trichloroacetic acid containing a tracer dose of $[^3H]$cAMP. Toxin addition to CT_m significantly increased the SCC over control values after 60 min; however, the SCC of CT_s tissues increased slowly but steadily until, 280 min after toxin addition, it was significantly greater than that of CT_m tissue. Conductance was decreased 25% by CT_m 120 min after toxin addition, but was not affected by CT_s. CT_m inhibited the SCC increase produced by theophylline to less than 20% of control values by 180 min after toxin addition, whereas CT_s inhibited the SCC response to theophylline to 41% of control values by 280 min after toxin was added. Conductance of CT_m and CT_s tissues, unlike control tissues, was not significantly decreased by theophylline added 280 min after toxin. CT_m decreased Na^+ flux in both directions and the Cl^- flux from the mucosal to the serosal side, producing net Cl^- secretion. CT_s changed the Cl^- flux slightly in the secretory direction. CT_m and CT_s increased cAMP equally, when measured 190 min after toxin and 10 min after theophylline administration. Addition of toxin to both sides produced an additive increase in cAMP. The results suggest that much of the toxin-stimulated cAMP content of the mucosa is not coupled to secretion and that active secretion is probably stimulated by cholera toxin added on the serosal side, although more slowly than after addition to the mucosal side.

1010 STIMULATION OF CDP-CHOLINE BIOSYNTHESIS BY ENANTIOMERIC LYSOPHOSPHATIDYLCHOLINES IN RAT INTESTINAL MUCOSA.

(Eng.) O'Doherty, P. J. A.; Smith, N. B.; Kuksis, A. (Dept. Biochemistry, Univ. Wisconsin, Madison, WI 53706). *Arch. Biochem. Biophys.* 180(1):10-18; 1977.

The effects of several molecular species of 3-*sn*-lysophosphatidylcholine and of 1-*sn*-lysophosphatidylcholine on the activity of phosphorylcholine cytidyltransferase were investigated in rat intestinal cells. The phosphorylcholine cytidyltransferase activity of the cytosol fractions of rat intestinal crypt and villus cells was stimulated by the addition of 3-*sn*-lysophosphatidylcholine. A 15- to 20-fold increase in activity was seen following a prior removal of phospholipids with acetone and butanol. 3-*sn*-Lysophosphatidylcholines of C_{16} and C_{18} carbon fatty acids were three to four times more effective than those with fatty chains of shorter length. The 3-*sn*-phosphatidyl and 3-*sn*-lysophosphatidyl ethanolamine, inositol, and serine were ineffective. 3-*sn*-Lysophosphatidic acid and 3-*sn*-glycerophosphorylcholine did not stimulate the transferase activity, indicating that both fatty acyl and phosphorylcholine moieties of the 3-*sn*-lysophosphatidylcholine molecule were required for the observed effect. Addition of the enantiomeric 1-*sn*-lysophosphatidylcholine had an effect comparable to that of 3-*sn*-lysophosphatidylcholine on the phosphorylcholine cytidyltransferase activity when assayed in rat intestinal mucosa and in pigeon liver. It is suggested that the stimulatory effect of lysophosphatidylcholine may be related to a specific detergent property dependent upon the peculiar balance of hydrophilic and hydrophobic components in the molecule.

1011 INTESTINAL BRUSH BORDER AND LYSOSOMAL ENZYMES AND IMMUNOGLOBULIN ABSORPTION IN THE NEWLY-BORN LAMB. (Eng.) Healy, P. J. (Veterinary Res. Station, Glenfield, New South Wales, 2167, Australia). *Aust. J. Exp. Biol. Med. Sci.* 55(3):327-337; 1977.

The activities of the brush border enzymes alkaline phosphatase, leucine aminopeptidase, and lactase and the lysosomal enzymes α-mannosidase and β-*N*-acetylglucosaminidase were studied in newborn lambs fed colostrum. The objective was to determine whether the release of intestinal alkaline phosphatase into the circulation of these lambs is a consequence of absorption of immunoglobulins. In fed lambs (0-36 hr after birth), there were differences in enzyme activities in intestine and the serum, e.g., both alkaline phosphatase and α-mannosidase activities increased in serum but at 9 hr after birth intestinal alkaline phosphatase activity was higher ($p<0.001$) and intestinal α-mannosidase activity was lower in lambs fed colostrum than in fasted lambs. In lambs fed colostrum, serum globulin concentration increased with time until 15 hr after birth (mean concentration at 15 hr, 59.8 ± 5.9 mg/ml). Feeding lipid and protein components of colostrum and bovine serum resulted in enzyme responses similar to those observed after feeding colostrum in lambs fed 0-3 hr after birth. The enzyme activities increased in mesenteric lymph collected from newly born lambs when immunoglobulins were being absorbed from the jejunum and ileum. The results are consistent with the hypothesis that proteins are absorbed by pinocytosis and then transported to the intracellular spaces of the serosal side of the cells.

1012 INDUCTION OF CHICK EMBRYONIC INTESTINAL DISACCHARIDASES BY HYDROCORTISONE AND SUCROSE IN THE ORGAN CULTURE SYSTEM. (Eng.) Yoshizawa, S.; Moriuchi, S.; Hosoya, N. (Sch. Health Sciences, Univ. Tokyo, 3-1, Hongo 7, Bunkyo-ku, Tokyo 113, Japan). *J. Nutr. Sci. Vitaminol.* 23(3):227-235; 1977.

The effect of hydrocortisone and sucrose on the development of intestinal disaccharidases was studied in the cultured chick intestine. When jejuna of 15- and 17-day-old embryos were cultured in the presence of hydrocortisone (10^{-8}-10^{-5} M), disaccharidase activity was significantly increased, compared with the control. However, hydrocortisone had no effect in 20-day embryonic intestines. On the other hand, the disaccharidase activity of cultured intestines from 20-day-old chick embryos was significantly stimulated by the addition of sucrose. The increase in disaccharidase activity induced by hydrocortisone administration in 17-day-old embryos *in vitro* was inhibited 60% by actinomycin D and 70-100% by cycloheximide. The activity induced by the administration of sucrose in 20-day-old embryos *in vitro* was sensitive to cycloheximide but insensitive to actinomycin D. The inhibition of hydrocortisone-evoked disaccharidase activity by the administration of an inhibitor of messenger RNA synthesis indicates that the hormonal action was mediated by an effect on messenger RNA synthesis. It appears that sucrose might act on the glycosylation of enzymes occurring in chick intestine at the 20-day stage.

1013 INFLUENCE OF THYROID ON THE DEVELOPMENT OF INTESTINAL HYDROLASES. (Spa.) Llorens, J. M. C. (Red Cross Hosp., Barcelona, Spain). *Rev. Iber. Endocrinol.* 23(135):276-287; 1976.

The activity and distribution in distinct intestinal segments of disaccharidases and the levels of thyroxine in the blood during the perinatal period were simultaneously investigated. Female Sprague-Dawley rats were mated, and their litters were reduced to eight pups per mother at birth. On designated days after birth, the pups were decapitated, exsanguinated, and the serum tested for thyroxine; their intestines were removed and cut into portions 2-10 cm away from the pylorus. The distribution of the different disaccharidases was homogeneous throughout the intestinal segments tested. Values for sucrase and maltase increased, whereas lactase levels decreased with increasing age of the animals. Maltase values were 55.8 ± 21 U/g at 1-5 days, 31 ± 21 U/g at 9-13 days, and 135 ± 50 U/g at 13-33 days. Lactase levels at the same age intervals were 66 ± 18.8 U/g, 28 ± 21.4 U/g, and 10.2 ± 12.9 U/g, resp. On the other hand, the thyroxine levels were practically undetectable at birth (<0.05 μg/100 ml) and rapidly increased to the adult value (3.8 μg/100 ml) at 22 days after birth. It is concluded that the thyroid gland plays an important role in the intestinal maturation of rats.

1014 LIPOLYTIC ACTIVITIES AGAINST TRIOCTANOIN AND MONOOLEIN IN RAT INTESTINAL MUCOSA. (Eng.) Negrel, R.; Serrero, G.; Ailhaud, G. (Centre de Biochimie, Parc Valrose, 06034 Nice, France). *Biochimie* 59(4):433-438; 1977.

The hydrolysis of trioctanoin and of monoolein by rat intestinal homogenates, catalyzed by the previously described "trioctanoin hydrolase" and "monoglyceride lipase," was studied. The hydrolysis rate of trioctanoin catalyzed by homogeneous intestinal glycerol-ester hydrolase was 0.1% of that of tributyrin, indicating that this enzyme does not account for all the activity observed against trioctanoin (0.17 U/mg against a calculated value of 0.005 U/mg) in the homogenate. Treatment with 0.1 mM diisopropyl phosphofluoridate, a glycerol-ester hydrolase inhibitor, caused no inhibition of triolein hydrolysis and some inhibition of trioctanoin hydrolysis. Tributyrin and dioctanoin hydrolysis was inhibited incompletely, while *p*-nitrophenylacetate hydrolysis was completely inhibited by diisopropylphosphofluoridate. Pancreatic lipase is known to remain fully active after diisopropylphosphofluoridate treatment;

tributyrin, trioctanoin, and dioctanoin are hydrolyzed by both glycerol-ester hydrolase and pancreatic lipase, while *p*-nitrophenylacetate and triolein are only cleaved by glycerol-ester hydrolase and by lipase, resp. It is therefore concluded that contaminating pancreatic lipase, together with glycerol-ester hydrolase, is responsible for trioctanoin and monoolein hydrolysis. Only 12% of the trioctanoin hydrolase activity was recovered at pH 7.5 in the supernatant fraction of the homogenate. Alkaline treatment of the resulting pellet lead to a 70% recovery of the activity measured with either trioctanoin or triolein as substrates. Diethylaminoethane (DEAE)-cellulose chromatography at pH 7.5 showed that all octanoin hydrolase and triolein hydrolase activity was eluted with the breakthrough volume, whereas 90% of the tributyrin hydrolase activity was retained. Immunoprecipitation studies showed complete precipitation of the activity measured against tributyrin and trioctanoin as substrates. Identical equivalence points were found with the pH 8.5 supernatant, the cationic fraction, and the homogeneous rat pancreatic lipase using immunoserum against rat pancreatic juice. The results support the conclusion that trioctanoin and monoolein hydrolyses are due entirely to the action of intestinal glycerol-ester hydrolase and to contaminating pancreatic lipase bound to the intestinal cells.

1015 CHARACTERISTICS AND POSTNATAL DEVELOPMENT OF THE ACID LIPASE ACTIVITY OF THE RAT SMALL INTESTINE.

(Eng.) Coates, P. M.; Brown, S. A.; Jumawan, J.; Koldovsky, O. (Children's Hosp. Philadelphia, Philadelphia, PA 19104). *Biochem. J.* 166(3):331-338; 1977.

For the first time, acid lipase was identified in the rat small intestine by using esters of 4-methylumbelliferone as substrates; its biochemical characteristics and changes in its activity in various sections of the small intestine during early postnatal development are described. Maximum activity towards the oleate ester was found at pH 4.0. In adult animals, the activity of acid lipase exhibited both latency and sedimentability, indicating a lysosomal localization. The activity of acid lipase was practically the same along the height of the villus, thus paralleling the distribution of acid β-galactosidase. In adult rats, the activity of acid lipase in proximal jejunum and mid-jejunum sections of the small intestine was practically the same and exceeded the activity in the ileum by a factor of 2. In suckling rats, the activity of the enzyme in the mid-jejunum exceeded that in the proximal jejunum and ileum by 2.5- and 1.5-fold, resp. During postnatal development, the acid lipase activity of the mid-jejunum showed a peak between days 10 and 15, at which time it exceeded the adult mid-jejunum activity by five- to sixfold. The results of the pH-dependency experiments, studies of the distribution of the enzyme activities, and latency studies suggest the presence of more than one lipolytic activity hydrolyzing esters of 4-methylumbelliferone.

1016 METABOLISM AND TRANSPORT OF GLUTAMINE AND GLUCOSE IN VASCULARLY PERFUSED SMALL INTESTINE RAT [sic].

(Eng.) Hanson, P. J.; Parsons, D. S. (Dept. Biochemistry, Univ. Oxford, South Parks Rd., Oxford OX1 3QU, England). *Biochem. J.* 166(3): 509-519; 1977.

The metabolism and transport of glutamine and glucose were investigated in a preparation of rat small intestine perfused through the vascular bed *in vitro* and *in situ*. With glucose (7.5 mM) or glutamine (4.5 mM) in the lumen, approximately 40% of the substrate taken up appeared to be unchanged on the vascular side. When glutamine (1.5 mM) was also added to the vascular perfusate, glutamine metabolism was increased, and glutamine was taken up from both the vascular bed and lumen. When glutamine was presented to the tissue from the lumen, there was greater conversion into alanine, and when glucose was presented to the intestine from the lumen, there was greater conversion into lactate. Deprivation of food and metabolic acidosis had no effect upon glutamine utilization by unit length of jejunum. In fed rats, glutamine utilization was 44% of glucose utilization, but in rats deprived of food, it was 112% of glucose utilization. Glucose utilization and lactate production were not significantly altered by the presence of glutamine in the vascular bed or lumen. With glucose only in the vascular perfusate, glucose utilization was the same in jejunum and ileum. Glutamine metabolism in the ileum was 28% lower than in the jejunum. Glutamine utilization was dependent on the concentration of glutamine in the vascular perfusate, but was not significantly affected by the absence of glucose.

1017 BIOSYNTHESIS OF BRUSH BORDER GLYCOPROTEINS BY HUMAN SMALL INTESTINAL MUCOSA IN ORGAN CULTURE.

(Eng.) Hauri, H. P.; Kedinger, M.; Haffen, K.; Freiburghaus, A.; Grenier, J. F.; Hadorn, B. (Dept. Pediatrics, Univ. Bern, Freiburgstr. 23, CH-3010 Bern, Switzerland). *Biochim. Biophys. Acta* 467(3):327-339; 1977.

The synthesis of brush border glycoproteins by human small intestinal mucosa from patients with morbid obesity was studied in organ culture by measuring the incorporation of ^{14}C-glucosamine into brush border membranes and the release of labeled proteins into the culture medium. Purified brush border membrane proteins were analyzed on polyacrylamide-sodium dodecyl sulfate gels. Nonsoluble proteins from the culture media were isolated for analysis by ultracentrifugation. Total ^{14}C-glucosamine (5 μCi/ml) incorporation into glycoproteins was measured by long-term and pulse labeling; incorporation into brush border proteins by culturing explants in the presence of ^{14}C-glucosamine (10 or 20 μCi/ml) and periodically harvesting specimens for analysis. There were no significant differences between the protein patterns after gel electrophoresis of cultured and noncultured explants. Radioactivity present in the tissue plus medium increased linearly over a period of 48 hr. Between 24 and 48 hr, the rate of incorporation into tissue leveled off, but release of labeled proteins into the medium increased. After 5 hr, label incorporation into isolated brush border membranes was found in peaks comigrating with markers of maltase-glucoamylase, lactase, sucrase-maltase, and enterokinase plus one unidentified peak. After 24 hr, a peak comigrating with alkaline phosphatase activity appeared as well as two more unidentified peaks. Incorporation of label into the nonsoluble fraction of the media revealed similar protein patterns. These results indicated that the brush border membrane remains functionally stable in organ culture, providing a useful system for studying the biosynthesis and molecular nature of glycoproteins produced by patients with congenital brush border enzyme deficiencies.

1018 PLASMA SECRETIN CONCENTRATION IN ANAESTHETIZED PIGS AFTER INTRADUODENAL GLUCOSE, FAT, AMINOACIDS, OR MEALS WITH VARIOUS pH. (Eng.)

Fahrenkrug, J.; Schaffalitzky de Muckadell, O. B.; Holst, J. J. (Dept. Clinical Chemistry, Bispebjerg Hosp., Copenhagen, Denmark). *Scand. J. Gastroenterol.* 12(3):273-279; 1977.

The concentration of immunoreactive secretin in portal blood and the secretion from the exocrine pancreas were measured during intraduodenal infusion of glucose, fat, amino acids, or meals with various pH in seven anesthetized Danish Landrace pigs. The solutions (50 ml each) were warmed to 37 C and infused for 1 min each in the following order after a 15-min basal period: 0.9% NaCl, 5.5% glucose, isotonic fat emulsion, isotonic amino acids, 0.1 M HCl, 9.0% NaCl, and 50% glucose. All solutions except HCl were adjusted to pH 7.0. The duodenum was drained 15 min after an infusion and the next test solution was infused 15 min after the draining (30 min after HCl). In another experiment, test meals composed of 1.5 g protein, 1.2 g fat, and 0.4 g carbohydrate was infused at several pH's (7.0, 5.0, 4.0, 3.0, 2.0, and 1.0) into the duodenum of four pigs. The levels of immunoreactive secretin in portal blood were not affected by any of the solutions except HCl, which caused the mean plasma secretin level to increase from 5.6 ± 2.7 to 201.2 ± 80.5 pM in 15 min. HCl increased the mean pancreatic flow rate from 0.51 ± 0.19 to 9.85 ± 2.33 ml/hr and the bicarbonate output from 52 ± 11 to 1,004 ± 290 μmol/hr. All solutions, except those of NaCl increased protein output significantly, and hypertonic glucose and HCl significantly increased amylase levels. The plasma secretin level was significantly increased only by the test meal at pH 1.0 (from 5.5 ± 2.8 to 115.0 ± 51.2 pM after 15 min). Pancreatic flow increased from 0.20 ± 0.08 to 6.25 ± 2.57 ml/hr. Amylase levels were increased after all meals. Several inconsistencies with the results of previous studies are discussed, as well as the possibilities that the amount of acid infused with each meal might have been too low and that anesthesia may have influenced the amount of pancreatic secretion. It is concluded that the physiological role of secretin could not be clearly defined by this study.

1019 LACK OF HEPATIC INACTIVATION OF CANINE VASOACTIVE INTESTINAL PEPTIDE. (Eng.)

Strunz, U. T.; Walsh, J. H.; Bloom, S. R.; Thompson, M. R.; Grossman, M. I. (Veterans Admin. Wadsworth Hosp. Center, Los Angeles, CA 90073). *Gastroenterology* 73(4):768-771; 1977.

Hepatic inactivation of vasoactive intestinal peptide (VIP) was studied in conscious dogs. In three animals with gastric fistula, the portal vein and inferior vena cava were transposed, thus allowing access to the portal vein through a hind leg vein. To demonstrate that the liver's ability to inactivate peptides was intact in these dogs, each experiment with VIP was preceded by an intraportal pentagastrin infusion (4 μg/kg/hr), which failed to stimulate acid secretion. In the tests with VIP, a plateau of acid secretion was established by systemic i.v. infusion of pentagastrin (1 μg/kg/hr). While continuing infusion of pentagastrin, VIP (0.5, 1.0, or 2.0 μg/kg/hr) was given by portal or systemic infusion for 30 min. VIP produced a dose-dependent decrease in acid secretion ranging from about 30% inhibition with the low dose to about 60% inhibition with the high dose. The degree of inhibition produced by portal infusion of VIP did not differ significantly from that produced by systemic infusion. After infusion of 30 μg/kg/hr of VIP for 5 min, peak serum VIP levels by radioimmunoassay were 769 ± 63 pM after systemic and 717 ± 60 pM after portal administration, an insignificant difference. After stopping the infusion, the disappearance half-time of VIP was 3.1 ± 0.3 min, which did not differ significantly with the two routes of administration. It is concluded that inhibition of acid secretion and serum levels of VIP were not significantly different after portal or systemic infusions of VIP. Thus, no evidence of selective hepatic inactivation of VIP was found in dogs.

1020 RELEASE OF VASOACTIVE INTESTINAL POLYPEPTIDE (VIP) BY INTRADUODENAL STIMULI [Abstract]. (Eng.)

GENERAL

1035 THE MECHANISM OF LINCOMYCIN-INDUCED DIARRHOEA. (Eng.) Hoff, S. G.; Schjonsby, H.; Andersen, K. J. (Univ. Clinic, Bergen, Norway). *Acta Med. Scand. (Suppl.)* 603:35-38; 1977.

To determine whether lincomycin-induced diarrhea is caused by bile acid malabsorption, metabolic studies were performed before and 7 days after treating rats p.o. with lincomycin (1 mg/ml drinking water). Following the treatment the mean fecal weight increased from 30.2 ± 3.8 g/72 hr to 65.5 ± 8.2 g/72 hr. The fecal fat excretion was unchanged, and the weight increase was mainly due to increased water content. The absorption rate of ^{14}C-taurocholic acid was measured in untreated rats and rats treated with lincomycin, using an *in vivo* perfusion technique. There was no significant difference in bile acid absorption rate measured at three different concentrations of bile acid (0.125, 0.500, 1.500 mM) in the perfusate. Although these results apparently exclude the hypothesis that lincomycin-induced diarrhea is caused by bile acid malabsorption, a back-wash ileitis might be present in this type of diarrhea and could explain bile acid malabsorption as a secondary phenomenon.

1036 PROTEIN-ENERGY MALNUTRITION IN INFANT NON-HUMAN PRIMATES (Macaca nemestrina). I.

CORRELATION OF BIOCHEMICAL CHANGES WITH FINE STRUCTURAL ALTERATIONS IN THE LIVER.

(Eng.) Enwonwu, C. O.; Worthington, B. S.; Jacobson, K. L. (Center for Res. Oral Biology, Univ. Washington, Seattle, WA). *Br. J. Exp. Pathol.* 58(1):78-94; 1977.

Possible correlations between biochemical changes and fine structural alterations were investigated in the livers of malnourished infant monkeys. Male infant pigtail monkeys *(Macaca nemestrina)* aged 6-9 months and born in captivity were fed a restricted amount of either an adequate protein diet (20% casein) or a protein-deficient diet (2% casein). After 3-5 months of receiving the low protein-containing diet, ultrastructural evaluation of hepatic parenchymal cells revealed extensive fatty metamorphosis, marked fragmentation and vesiculation of the rough endoplasmic reticulum, some evidence of distention of the nuclear membrane, a variable degree of mitochondrial polymorphism and gigantism, increased intracytoplasmic accumulation of glycogen particles, and enhanced prominence of collagen fibers in the intercellular and perisinusoidal spaces. Biochemical studies indicated severe distortion in the plasma profile of free amino acids by week 10 of malnutrition, with a prominent decrease in valine/glycine ratio (9% in the malnourished animals compared to a ratio of 55-63% in the control group). While plasma concentration of glycine was elevated above baseline value throughout the period of malnutrition, the level of alanine showed an initial rise followed by a significant drop (-58% at week 20). Although showing wide individual variation, the plasma level of corticosteroid in general tended to increase with duration of protein malnutrition, an observation consistent with the accumulation of glycogen and enlargement of mitochondria in the hepatic cells.

1037 DECREASED CONJUGATION OF *p*-AMINOBENZOIC ACID IN THE ICTERIC NEW BORN GUNN RAT.

(Eng.) Davis, D. R.; Yeary, R. A. (Dept. Veterinary Physiology, Ohio State Univ., Columbus, OH 43210). *Biochem. Pharmacol.* 26(6):535-539; 1977.

The metabolism of *p*-aminobenzoic acid in the icteric and nonicteric Gunn rat was studied. The urinary metabolites of *p*-aminobenzoic acid identified were the parent compound, *p*-aminohippuric acid, and *p*-aminobenzoic acid glucuronide. The icteric Gunn rat excreted significantly less *p*-aminobenzoic acid within 24 hr and also excreted significantly less of the compound as the glucuronide. In the newborn icteric rat, the major excretory product was the unchanged *p*-aminobenzoic acid, whereas in the adult most of the drug was excreted as the glycine conjugate. The data *in vivo* and *in vitro* indicated that the icteric newborn rat converts significantly less *p*-aminobenzoic acid to *p*-aminohippuric acid than does the nonicteric rat. The synthesis of *p*-aminohippuric acid was low in both genotypes at birth, but rapidly approached adult levels at 30 days of age. The increased toxicity of *p*-aminobenzoic acid in the 2-day-old icteric Gunn rat may be the result of a decreased *p*-aminobenzoic acid metabolism in these rats due to a deficiency in the activity of the enzyme uridine diphosphate-glucuronyltransferase and possibly glycine-*N*-acyltransferase.

1038 ANGIOGRAPHIC ASPECTS OF EXPERIMENTAL NONOCCLUSIVE INTESTINAL ISCHEMIC INJURY.

(Eng.) Bookstein, J. J.; Goldberger, L.; Niwayama, G.; Naderi, M. J.; Brahme, F. J.; Jones, T. A. (Univ. California Medical Center, 225 West Dickinson St., San Diego, CA 92103). *Am. J. Roentgenol.* 128(6):923-930; 1977.

Hypovolemic and normovolemic hypotensive models for nonocclusive ischemic injury were developed in mongrel dogs to investigate the accuracy of angiography in diagnosing the presence and extent of ischemic injury and to evaluate the therapeutic, prophylactic, or diagnostic values of papaverine as a vasodilator. Drugs, anesthesia, and contrast medium for angiography were administered through i.v. and intra-arterial (i.a.), catheters. In the hypovolemic model, nine dogs were bled into a reservoir through a catheter passed into the left femoral artery and blood pressure held at 40, 50 or 60 mm Hg for varying time intervals. The peritoneum and intestines were examined after sacrifice at 48 or 72 hr, or at spontaneous death. Normovolemic hypotension was studied in a similar model by injecting isotonic saline into the pericardial sac to reduce the blood pressure to 40 or 50 mm Hg for varying time intervals. Following the shock period, the pericardial fluid was withdrawn and blood pressure normalized. The hearts and intestines were examined either at sacrifice (24 hr) or at spontaneous death. Papaverine infusion (0.5 mg/min) into the superior mesenteric artery was begun at various intervals after the onset of shock and continued throughout the shock period in six dogs with normovolemic shock. Papaverine infusion (0.15 mg/ml, 0.033-0.075 mg/min) into a segmental ileac branch was begun with the onset of normovolemic shock and continued for 30-45 min (2 dogs) or for 2 hr (3 dogs). Arteriograms of the superior mesenteric artery were performed at regular intervals in 9 dogs with hypovolemic hypotension and in 17 dogs with normovolemic hypotension (with and without papaverine). Four of nine dogs died 1.5 to 4.5 hr after the onset of hypovolemic hypotension; ischemic injuries to the small bowel occurred in eight dogs, while the colon was affected in only one dog. On a scale of 0-4, the mean severity of the injuries was 1.67 ± 0.9, and was not affected by the amount and duration of hypotension. Six of 13 dogs died 1-3.5 hr after the onset of normovolemic shock; small bowel and colonic injury were more severe (3.5 ± 0.58) than in hypovolemic hypotension. Normovolemic hypotensive animals given papaverine survived until sacrifice (48 or 72 hr); the mean grade of injury in the 6 dogs receiving papaverine via the superior mesenteric artery was 0.92 ± 0.92, whereas it was 3.31 ± 0.59 in 12 normovolemic hypotensive dogs not given papaverine. Angiography and the post-papaverine vasodilator response did not reflect the nature or extent of injury in either the hypovolemic or normovolemic shock models. However, papaverine administered within 2 hr after the onset of normovolemic shock greatly reduced intestinal injury.

1039 THE EFFECT OF DIGITALIS ON REGIONAL ISCHAEMIA OF THE RAT SMALL INTESTINE.

(Eng.) Rentzhog, L.; Wikstrom, S. (Univ. Hosp., Uppsala, Sweden). *Upsala J. Med. Sci.* 81(3):179-182; 1976.

Digitoxin was administered to male Sprague-Dawley rats (in which iodine metabolism had been standardized) with induced regional intestinal ischemia to examine its effect on collateral circulation in the small bowel. Exchange circulation was analyzed 30 min after the transmural injection of a test dose of ^{131}INa into the lumen of the isolated intestinal loop. In one experiment, digitoxin (0.1 mg/100 g body weight, i.v.) was administered to 20 rats, and ischemia comprising 11 mesenteric end arcades was established 2 hr after the digitoxin was administered. The exchange circulation was examined 30 min later. The rats retained 50% of the radioactivity in the intestinal loop; whereas untreated ischemic animals and animals without ischemia retained 63 and 25%, resp. The results demonstrate that digitalis disrupts the collateral circulation in adjacent healthy intestine as well as in the small vessels in the intestinal loop. In another experiment, an ischemia comprising seven mesenteric end arcades was induced in 22 rats, followed by administration of digitoxin (0.1 mg/100 g, s.c. daily for 2 wk). The exchange circulation was then analyzed. Four of the treated rats died. After 2 weeks, the weight of rats treated with digitoxin had not changed, whereas untreated ischemic rats had increased their weight by 10%. The treated and untreated groups retained 42 and 37% of the radioactivity in the loop, resp. Disruption of collateral circulation was not observed in this test group, but the increased mortality and the absence of weight increase suggest that prolonged treatment with digitalis may have toxic effects.

1040 CLINDAMYCIN-ASSOCIATED COLITIS IN HAMSTERS: PROTECTION WITH VANCOMYCIN. (Eng.)

Bartlett, J. G.; Onderdonk, A. B.; Cisneros, R. L. (Veterans Admin. Hosp., 150 S. Huntington Ave., Boston, MA 02130). *Gastroenterology* 73(4):772-776; 1977.

The possible protective effects of gentamicin, vancomycin, and bacitracin on clindamycin- or lincomycin-induced colitis were investigated in male Syrian hamsters. The animals received lincomycin hydrochloride (2 mg/day, i.m.) or clindamycin phosphate (2 mg/day i.m. or i.p. or 0.1 ml/day, p.o.) for 3 days. Some animals received clindamycin intracecally (5 mg) at laparotomy. Clindamycin or lincomycin was fatal to 65 of 67 recipients during the 2-week observation period. The p.o. administration of gentamicin (2 mg/ml drinking water for 14 days starting 48 hr before initiating lincomycin or clindamycin treatment) prevented mortality in 7 of 11 animals challenged with lincomycin and 5 of 10 animals challenged with clindamycin. The best protective results were achieved with vancomycin and bacitracin. Bacitracin (3 mg/ml drinking water) prevented death in all 10 animals challenged with clindamycin. The simultaneous administration of vancomycin (3 mg/ml) with gentamicin (2 mg/ml) prevented death in all 10 animals challenged with clindamycin and all 9 animals challenged with lincomycin. The administration of vancomycin alone (3 mg/ml, p.o. or 10 mg/day, i.m.) for 14 days prevented death in all 30 animals that received clindamycin. There was no gross or microscopic evidence of intestinal lesions in the animals treated with vancomycin. Clindamycin administration resulted in minimal changes in total aerobic and anaerobic counts, although there was more than a 4-log increase in mean concentrations of coliforms. Vancomycin produced a similar increase in coliform concentrations and a marked decrease in clostridia counts, whereas no change was detected after clindamycin administration. The results demonstrate that vancomycin protects against a lesion in hamsters in which coliform bacteria would be the anticipated pathogens.

1041 ENTERIC FLORA OF NORMAL LABORATORY GUINEA-PIGS.

(Eng.) McLean, A. J.; Boquest, A. (Univ. Texas Health Science Center, San Antonio, TX 78284). *Br. J. Exp. Pathol.* 58(3):251-254; 1977.

The bowel flora of guinea pigs was studied using nonselective cultural conditions and conditions highly selective for *Escherichia coli* organisms. No *E. coli* were cultured from adult or juvenile bowel content. Parallel studies showed that culture media supported the growth of small numbers of reference *E. coli* "seeded" into them along with bowel content. It is concluded that normal adult laboratory guinea pigs may be bacteriologically equivalent to the NCS strain of "*E. coli*-free" mice, and it appears, therefore, to represent an experimental model for the study of endotoxin toxicity mechanisms.

1042 ROLE OF COLONIC BACTERIA IN THE PATHOPHYSIOLOGY OF FECAL PERITONITIS. (Eng.)

Rink, R. D.; Short, B. L.; Van, N. V.; Fry, D. E. (Univ. Louisville Health Sciences Center, Louisville, KY 40201). *Circ. Shock* 4(3):259-270; 1977.

The role of colonic bacteria in the reactions accompanying fecal peritonitis was investigated in male Sprague-Dawley rats. Septic or nonseptic peritonitis was induced by the administration through an abdominal incision of fresh fecal suspensions or suspensions pretreated with heat or antibiotic. Measurements during 8 hr in rats with septic peritonitis recorded bacteremia, hypoglycemia and progressive hemoconcentration, lactacidemia, and hypocapnea. Mortality was 100% by 24 hr. Nonseptic peritonitis produced significantly lesser degrees of hemoconcentration and hypocapnea. Plasma lactate remained in control ranges, while plasma glucose concentrations increased slightly. Mortality was 5% in 24 hr. The same parameters in control rats were stable over 8 hr. Hepatic oxygen supply was estimated in each group by multiple platinum wire electrodes. Severe hepatic hypoxia was recorded by 6 hr in rats with septic peritonitis (PO_2=3.0 mm Hg). By contrast, nonseptic peritonitis caused a comparatively mild degree of hypoxia (9.5-10.9 mm Hg) in comparison with that in controls (16.8 mm Hg). The pathophysiologic developments in septic rats appear to be largely the result of hypovolemia induced by colonic bacteria. The administration of a colloid solution (4% Ficol 70 in 0.9% saline) was effective in preventing its development.

1043 EFFECT OF NEONATAL GASTROINTESTINAL COLONIZATION WITH CROSS-REACTING Escherichia coli ON ANTICAPSULAR ANTIBODY PRODUCTION AND BACTEREMIA IN EXPERIMENTAL Haemophilus influenzae TYPE b DISEASE OF RATS. (Eng.) Myerowitz, R. K.; Norden, C. W. (Presbyterian-Univ. Hosp., Pittsburg, PA 15213). *Infect. Immun.* 17(1):83-90; 1977.

Experiments were carried out to determine whether neonatal gastrointestinal colonization by cross-reacting *Escherichia coli* induces protection against experimental *Haemophilus influenzae* type b (HIb) infection. Neonatal gastrointestinal colonization of newborn rats with *E. coli* 075:K100:H5, cross-reactive with the capsular polysaccharide of HIb, was harmless but failed to stimulate detectable (>200 ng/ml) serum anticapsular antibodies. Neonatally colonized rats, when challenged at age 13 weeks by i.p. inoculation of HIb, showed no difference in the frequency, magnitude, or duration of bacteremia or in the postinfection anticapsular antibody response when compared with saline-fed controls. However, neonatally colonized rats challenged at age 4 weeks had a significantly decreased incidence of sustained bacteremia and/or endophthalmitis when compared with controls. This decreased frequency of disease correlated with a significant increase in postinfection serum anticapsular antibodies. Neonatal gastrointestinal colonization with cross-reacting *E. coli* appears to "prime" the young host to respond to infection with HIb with an anticapsular antibody response that protects against sustained HIb bacteremia and its complications.

1044 THYMUS DEPENDENCE AND INDEPENDENCE OF INTESTINAL PATHOLOGY IN A Trichinella spiralis INFECTION: A STUDY IN CONGENITALLY ATHYMIC (NUDE) MICE. (Eng.) Ruitenberg, E. J.; Leenstra, F.; Elgersma, A. (Natl. Inst. Public Health, P.O. Box 1, Bilthoven, Netherlands). *Br. J. Exp. Pathol.* 58(3):311-314; 1977.

The hypothesis that nonspecific histopathological gut changes are thymus-dependent was tested in a *Trichinella spiralis* infection. The study was performed in congenitally athymic (*nu/nu*) mice and their thymus-bearing heterozygous litter mates (+/*nu*). The nonspecific histopathological changes of the small intestine were judged on villus/crypt ratio and mitotic index; for the specific (immunological) reaction the number of pyroninophilic cells in the small intestine was used as criterion. *T. spiralis* induced nonspecific histopathological reactions both in *nu/nu* and +/*nu* mice, whereas the number of pyroninophilic cells was only increased in +/*nu* mice. It is concluded that the immunological reaction was dependent on the immune status of the host, whereas the nonspecific histopathological changes were not (i.e., they were thymus-independent)

1045 EARLY LESIONS OF PANCREATIC DUCTAL CARCINOMA IN THE HAMSTER MODEL. (Eng.) Pour, P.; Althoff, J.; Takahashi, M. (Eppley Inst. for Res. in Cancer, 42nd and Dewey Ave., Omaha, NB 68105). *Am. J. Pathol.* 88(2):291-303; 1977.

The site of pancreatic ductal carcinoma origin was investigated by analyzing the sequence of events in pancreatic carcinogenesis in a hamster model. Syrian golden hamsters were treated s.c. weekly with *N*-nitrosobis(2-oxopropyl)amine (10 mg/kg) for life (group 1) or 6 weeks and were sacrificed at biweekly intervals from 2 weeks (group 1) and 8 weeks (group 2) after initiation of the experiment. The pancreas was examined in step sections, and the sequential alterations noted for each interval were recorded. Lesions were found in intrapancreatic and extrapancreatic ducts. Equivalent alterations consisting of hyperplasia, metaplasia, atypia, and lesions characteristic of carcinoma *in situ* developed ubiquitously and simultaneously in pancreatic ducts of different sizes and in ductules, but not in acinar cells. Among the most significant findings were intrainsular ductular formations, their proliferation, and sequential malignant alteration comparable to the involved pre-existing ductules. Differences between the two experimental groups were of a quantitative rather than qualitative nature. The results indicate a common origin of all induced tumors from a pluripotent cell populating the pancreatic ductal system.

1046 HYPEROSMOLALITY AND PANCREATIC BLOOD FLOW. (Eng.) Jarhult, J.; Thulin, A. (Dept. Physiology, Univ. Lund, Solvegatan 19, S-22362 Lund, Sweden). *Pfluegers Arch.* 370(2):127-130; 1977.

The possible role of regional hyperosmolality in functional pancreatic hyperemia was studied in the cat pancreas. Close intra-arterial infusions of hypertonic xylose, glucose, and sucrose solution (30-50%) caused a marked vasodilatation but no secretion. The magnitude of the vasodilator response correlated with the degree of induced glandular hyperosmolality but not with the substance per se. The initial decrease of vascular resistance (peak response) averaged about 35% of the control value, whereas the steady-state response was 60-70% of the control value. Stimulation of the vagus nerve as well as infusion of secretin and/or cholecystokinin evoked a pronounced secretion and a small to moderate increase in pancreatic blood flow (peak increase 130-225% of control), but did not significantly change the plasma osmolality in the venous effluent from the gland. Bradykinin, papaverine, and isoproterenol caused large increments of pancreatic blood flow; none of these drugs evoked secretion, nor did they change the venous osmolality. It is concluded that blood-borne hyperosmolality is a strong stimulus for pancreatic vasodilatation, but the functional hyperemia of this gland is due to factors other than regional tissue hyperosmolality.

1047 SELF-REGULATION OF REGIONAL CIRCULATION IN THE PANCREAS. EFFECT OF PERIPHERAL VENOUS INTRAMURAL STIMULATION. 4. INFLUENCE OF ATROPINE. (Ita.) Musca, A.; Marigliano, V.; Cordova, C.; Cammarella, I. (VI Cattedra di Semeiotica Medica, Universita di Roma, Rome, Italy). *Boll. Soc. Ital. Biol. Sper.* 52(16):1215-1218; 1976.

The influence of atropine on pressor valve response was studied in the pancreas of the dog. Percentage variation in pancreatic circulation was measured at 15-min intervals beginning at 30 min and continuing for 3 hr after i.v. administration of 30 μg/kg atropine sulfate. Peak variations from baseline values occurred between 30 min and 2 hr after treatment. Atropine sulfate is capable of interrupting pressor response at the point of expression of the vascular region of the pancreas but not in the intramural peripheral veins.

1048 SELF-REGULATION OF REGIONAL CIRCULATION IN THE PANCREAS. EFFECT OF PERIPHERAL VENOUS INTRAMURAL STIMULATION. 5. INFLUENCE OF SODIUM PENTOBARBITAL. (Ita.) Marigliano, V.; Musca, A.; Cordova, C.; Cammarella, I. (VI Cattedra di Semeiotica Medica, Universita di Roma, Rome, Italy). *Boll. Soc. Ital. Biol. Sper.* 52(16):1219-1222; 1976.

The influence of sodium pentobarbital on pressor valve response was studied in the pancreas of the dog. Percentage variation in pancreatic circulation was measured at 15-min intervals beginning at 30 min and continuing for 3 hr after i.v. administration of 30 μg/kg sodium pentobarbital. Sodium pentobarbital interrupts pressor response at the point of expression of the vascular regions of the pancreas but not in the peripheral veins.

1049 EXPERIMENTAL STUDY OF THE SELF-REGULATION OF REGIONAL CIRCULATION IN THE PANCREAS. EFFECT OF PERIPHERAL VENOUS INTRAMURAL STIMULATION. 6. INFLUENCE OF HISTAMINE. (Ita.) Musca, A.; Marigliano, V.; Cordova, C.; Cammarella, I. (VI Cattedra di Semeiotica Medica, Universita di Roma, Rome, Italy). *Boll. Soc. Ital. Biol. Sper.* 52(16): 1223-1228; 1976.

The influence of histamine on pressor valve response was studied in the pancreas of the dog. Percentage variation in pancreatic circulation was measured at 15-min intervals beginning at 30 min and continuing for 3 hr after i.v. administration of 30 μg/kg histamine. Histamine does not inhibit pressor response in the peripheral veins but rather intensifies it. Pancreatic circulation increases with time in a prolongation of the phenomenon after administration of the drug.

1050 PANETH CELLS IN EXPERIMENTAL AMYLOIDOSIS. (Eng.) Ahonen, A.; Penttila, O.; Klinge, E. (Dept. Pharmacology, Univ. Helsinki, Siltavuorenpenger 10 A, SF-00170 Helsinki 17, Finland). *Scand. J. Gastroenterol.* 12(2):129-133; 1977.

The effect of experimental amyloidosis on the morphology of mouse Paneth cells was investigated, using light and fluorescence microscopy. Amyloidosis was induced by daily s.c. casein injections (0.2 ml) for 4 weeks. The number of secretory granules of the Paneth cells increased in the jejunum ($p<0.001$), but remained normal in the duodenum. Small morphological alterations took place in the Paneth cells during the induction of amyloidosis, and occasionally the Paneth cells were totally lost. These changes suggest that the function of the Paneth cells of the jejunum may be partly inhibited during experimental amyloidosis.

1051 PURIFICATION OF HOG GASTRIC INTRINSIC FACTOR BY A SIMPLE TWO-STEP PROCEDURE BASED ON AFFINITY CHROMATOGRAPHY AND A SELECTIVE GUANIDINE HYDROCHLORIDE GRADIENT. (Eng.) Francis, G. L.; Smith, G. W.; Toskes, P. P.; Sanders, E. G. (Veterans Admin. Hosp., Gainesville, FL 32602). *Gastroenterology* 72(6):1304-1307; 1977.

A method for the separation of intrinsic factor (IF) from NIF (a vitamin B_{12}-binding glycoprotein not active in promoting vitamin B_{12} absorption) is described. Monocarboxylic acid derivatives of vitamin B_{12} were covalently coupled to 1,6-hexanediamine-substituted Sepharose by using a water-soluble carbodiimide resulting in 1.32 μmol of B_{12} coupled per ml of Sepharose. After a source of crude hog IF was passed over the column, a selective linear gradient of guanidine HCl (0-4.0 M) was used to remove IF and 4.0-7.5 M to elute NIF. Anti-IF antibodies blocked 99% of the B_{12} binding by the isolated IF and only 1% of the B_{12} binding by NIF. Passage over a hydroxyapatite column resulted in IF 99% pure with a specific activity of 29.8 μg of B_{12} binding per mg of protein. IF so isolated exhibited one homogeneous band on polyacrylamide gel electrophoresis and corrected B_{12} malabsorption in a patient with pernicious anemia.

1052 ANTHELMINTIC DIHYDROQUINOXALINO[2,3-b]-QUINOXALINES. (Eng.) Fisher, M. H.; Lusi, A.; Egerton, J. R. (Merck and Co., Inc., Rahway, NJ 07065). *J. Pharm. Sci.* 66(9):1349-1352; 1977.

DIAGNOSTIC PROCEDURES

1082 EMERGENCY DIAGNOSIS OF UPPER GASTROINTESTINAL BLEEDING BY FIBEROPTIC ENDOSCOPY. (Eng.) Villar, H. V.; Fender, H. R.; Watson, L. C.; Thompson, J. C. (Univ. Texas Medical Branch, Galveston, TX 77550). *Ann. Surg.* 185(3):367-374; 1977.

Experience with 192 patients in whom emergency esophagogastroduodenoscopy was used in the diagnosis and treatment of massive upper gastrointestinal bleeding is presented. Accurate endoscopic diagnosis was made in 184; 58 patients underwent emergency operations to control bleeding with an overall operative mortality of 26%. Excluding 16 patients who underwent emergency portacaval shunting, the operative mortality was 7%. In six patients, the bleeding was controlled by endoscopic electrocoagulation. There were no complications. Emergency endoscopy should be done routinely as the primary diagnostic approach in the diagnosis of upper gastrointestinal bleeding.

1083 ELECTRICAL ASSESSMENT OF FUNCTIONAL LACTASE ACTIVITY IN CONSCIOUS MAN. (Eng.) Read, N. W.; Davies, R. J.; Holdsworth, C. D.; Levin, R. J. (Dept. Medicine, Univ. Sheffield, Sheffield S10 2TN, England). *Gut* 18(8):640-643; 1977.

The hypothesis that the magnitude of the lactose potential may reflect the functional lactase activity in the small intestine was tested. Using an electrical technique for measuring transjejunal potential differences (PDs) in conscious man, the electrogenic absorption of the hexoses liberated by hydrolysis of lactose was estimated. Lactose was infused into the jejunum of 1 normal control and 21 patients with diarrhea. The results were compared with jejunal lactase levels determined from biopsy specimens taken from the recording site immediately after infusion. The PD evoked by 100 mM lactose was significantly lower in patients with lactase levels below 4 U (lactase deficient) compared with subjects with normal lactase levels. There was also a significant correlation ($r=0.87$, $p<0.005$) between the magnitude of the lactose potential (expressed as the ratio of the maximum glucose transfer potential) and the mucosal lactase level in the hypolactasic subjects, but not in patients with normal lactase levels. Thus, in the subjects with lactase deficiency, the electrogenic transfer of hexose is clearly limited by the rate of lactose hydrolysis. Unlike other assessments of functional lactase activity, the electrical test provides a specific index of jejunal function and, moreover, can be adapted to investigate the possible disorders of small intestinal motility and secretion associated with hypolactasia.

1084 $^{14}\mathrm{CO}_2$ EXHALATION TEST. A NEW DIAGNOSTIC TOOL IN GASTROENTEROLOGY. (Ger.) Adlung, J.; Kelch, L.; Pancho, W.; Grazikowske, H.; Uthgennant, H. (I. Medizinische Klinik, Medizinische Hochschule Lubeck, Kronsforder Allee 71/73, D-2400 Lubeck, W. Germany). *Z. Gastroenterol.* 14(5):565-573; 1976.

The diagnostic value of three $^{14}\mathrm{CO}_2$ exhalation tests (^{14}C-tripalmitate fat resorption test, ^{14}C-lactose resorption test, and ^{14}C-glycocholic acid test) was studied in normal subjects and in patients with gastrointestinal diseases. The tripalmitate resorption test was performed in 20 normal subjects, in 18 patients with chronic recurrent pancreatitis without manifest pancreatic insufficiency, and in 8 patients with advanced malassimilation syndrome. The percentage of $^{14}\mathrm{CO}_2$ exhaled in 8 hr by the normal subjects averaged 9.1%. The $^{14}\mathrm{CO}_2$ exhalation was significantly reduced only in the patients with advanced malassimilation syndrome. The percentage of $^{14}\mathrm{CO}_2$ exhaled in 4 hr in the lactose resorption test averaged 11.9 ± 0.6% in 27 healthy controls, showing no significant difference in 16 patients with and without lactase deficiency who had undergone Billroth-II resection, nor in 6 patients with malabsorption and lactase deficiency. The glycocholic acid test was performed in 22 normal subjects, 8 patients with suspected bacterial infection of the small intestine, and in 11 patients with resected ileum or Crohn's disease. Significantly decreased $^{14}\mathrm{CO}_2$ exhalation was found in 16/19 patients, but false-negative results were obtained for 3 patients with resected ileum. Differentiation between bile salt malabsorption and bacterial infection was, however, impossible. The findings indicate the small value of the $^{14}\mathrm{CO}_2$ exhalation tests in gastroenterological disorders. Simplicity and convenience alone are not enough to recommend these tests.

1085 RADIOLOGICAL DIAGNOSIS OF TUMORS OF THE SMALL INTESTINE. (Ger.) Scherer, K.; Bucheler, E.; Erbe, W. (Radiologische Klinik, Universitatskrankenhaus Hamburg-Eppendorf, Martinistrasse 52, 2000 Hamburg 20, W. Germany). *Roentgenblaetter* 30(8):379-387; 1977.

The possibilities for radiologic diagnosis of tumors of the small intestine are reviewed. Barium x-ray; pharmacoradiological methods with cerulein; enteric-coated capsules of tartaric acid, sodium hydrogen carbonate, and dimethylpolysiloxane; Pro-Banthine or Buscopan; angiographic methods; and especially Sellink's probing method are suitable for the diagnosis of small intestinal tumors. The fractionated gastrointestinal passage method is problematic due to the possible superposition of intestinal loops in the small pelvis, and to the high time requirement for the examination. Angiography is especially suitable for the diagnosis of vascularized tumors with extramural spread, such as leiomyoma, neurinoma, hemangioma, and even carcinoid and duodenal carcinoma, despite their low degree of vascularization. Such poorly vascularized tumors as adenomas, lipomas, fibromas, neurofibromas, adenocarcinomas, metastases, and lymphoreticular sarcomas require intestinal passage tests for diagnosis.

1086 CARCINOEMBRYONIC ANTIGEN IN COLONIC LAVAGE. (Eng.) Winawer, S. J.; Fleisher, M.; Green, S.; Bhargava, D.; Leidner, S. D.; Boyle, C.; *et al.* (Memorial Hosp., 1275 York Ave., New York, NY 10021). *Gastroenterology* 73(4, Part 1):719-722; 1977.

Colonoscopic lavage was performed for assay of carcinoembryonic antigen (CEA) concentration in 35 patients with small and large colonic adenomas, in 11 patients with adenocarcinoma of the colon, and in 12 normal controls. CEA analyses were carried out in perchloric acid extracts of both colonic and plasma specimens by Sephadex G-200 gel column chromatography and electrophoresis. CEA concentration was considerably higher in colonoscopic lavage as compared to plasma. CEA concentration in normal controls (266 ng/mg protein) and in patients with colonic adenomas <1 cm in size (372 ng/mg) were not significantly different. CEA concentrations in patients with colonic adenomas >1 cm in size (1,151 ng/mg) and in patients with adenocarcinoma of the colon (1,509 ng/mg) were significantly higher than those observed in patients with small adenomas and in the normal controls. In all except two patients, plasma CEA concentrations were normal. Assay of CEA concentrations in colonic lavage may have potential application in the further assessment of the mucosa at risk for colon adenomas and for colon cancer. It does not appear to be accurate enough for diagnosis of colon cancer in individual patients.

1087 ENDOSCOPY AND POLYPECTOMY FOR THE EARLY DETECTION OF CARCINOMA OF THE RECTUM AND THE COLON (METHODS, SIGNIFICANCE, AND LIMITATIONS).

(Ger.) Otto, P.; Helmstaedt, D. (Medizinische Abteilung, Kreiskrankenhaus Grossburgwedel, 3006 Burgwedel 1, W. Germany). *Roentgenblaetter* 30(8): 400-407; 1977.

The state of the art of endoscopy in the early diagnosis and treatment of colorectal polyps and carcinomas is described. As routine rectoscopy is not justified in screening, it should be restricted to patients with occult blood in the feces and suspect anamnesis (perianal bleeding, irregular bowel movements, and abdominal spasms). If carcinoma is found rectoscopically, double-contrast x-ray examination should be performed in view of the possibility of double carcinoma. Coloscopy is necessary, if the source of the bleeding is not detected by rectoscopy or x-ray examinations. High coloscopy should be reserved for use in clinics, while sigmoidoscopy can be performed routinely. All colorectal polyps should be completely removed for correct histological diagnosis. Endoscopic polypectomy is an effective curative therapy, and surgery is necessary only in the case of polyps invading the muscular layer. In a series of 18,814 diagnostic and 3,490 therapeutic coloscopies, the mortality rate was 0.026% versus 1-1.5% after transabdominal colostomy with polypectomy.

1088 ARTERIOGRAPHY IN MALIGNANT NEOPLASMS OF THE BOWEL.

(Eng.) Campbell, D. R.; Mason, W. F.; Fraser, D. B.; Standen, J. R. (Victoria General Hosp., Halifax, Nova Scotia B3H 2Y9, Canada). *J. Can. Assoc. Radiol.* 28(3):204-207; 1977.

Experience with arteriography in the investigation of gastrointestinal bleeding and in the diagnosis of malignant bowel neoplasms is presented. Eighty patients with gastrointestinal bleeding were investigated by angiography over a 4-yr period. Nine had malignant neoplasms of the bowel, and the case reports of four of these patients are presented. Inconspicuous neovascularity was the most constant finding, best seen in leiomyosarcoma of the small bowel and adenocarcinoma of the colon. Neovascularity was not seen in a patient with reticulum cell sarcoma of colon, detected by extravasation. In two of the patients whose case reports are presented, the malignancies were missed by standard barium studies; these lesions involved the jejunum and ascending colon, resp. When other studies including endoscopy and barium examinations have failed to explain acute or chronic bleeding, an appreciable number of intestinal neoplasms may be demonstrated by arteriography.

1089 "HOT SPOT" ON HEPATIC SCINTIGRAPHY AND RADIONUCLIDE VENACAVOGRAPHY.

(Eng.) Gooneratne, N. S.; Buse, M. G.; Quinn, J. L., III; Selby, J. B. (Medical Univ. South Carolina Hosp., 80 Barre St., Charleston, SC 29401). *Am. J. Roentgenol.* 129(3):447-450; 1977.

Seven patients showing a localized area of increased uptake (hot spot) on ^{99m}Tc sulfur colloid liver scans are described. Dynamic studies were also carried out in four of the patients. The hot spot was associated with superior vena caval obstruction in five patients, with inferior vena caval obstruction in one, and with a hepatoma in one. Clinical evidence of vena caval obstruction was present in only three cases. Although a hot spot on static liver images usually indicates superior vena caval obstruction, the addition of radionuclide venacavography is recommended to confirm the diagnosis. A hot spot in the liver area in a radionuclide venogram of the lower limbs suggests inferior vena caval obstruction with collaterals via the liver.

1090 RADIOLOGIC SPECTRUM OF MELANOMA METASTATIC TO THE GASTROINTESTINAL TRACT.

(Eng.) Goldstein, H. M.; Beydoun, M. T.; Dodd, G. D. (M. D. Anderson Hosp. and Tumor Inst., Houston, TX 77030). *Am. J. Roentgenol.* 129(4):605-612; 1977.

Radiologic experience with 67 cases of metastatic melanoma involving the gastrointestinal tract is presented. The areas of involvement included the esophagus (5 cases), stomach (16 cases), duodenum (13 cases), small intestine (32 cases), colon (3 cases), liver (10 cases), gallbladder (3 cases), biliary tree and pancreas (4 cases), and mesentery and omentum (12 cases). Three patients with gastroduodenal lesions had a solitary nodule in the stomach that was detected only by double contrast examination. The intramural nodule was the most commonly encountered melanoma lesion in the stomach and duodenum. The nodules varied considerably in size. Approximately an equal number were present with and without a central ulceration, and both types of nodules were frequently encountered in the same patient. In two instances, gastric tumors also had a large extragastric component. The largest diversity of radiologic presentations of melanoma metastases occurred in the small intestine. A frequent manifestation was also one or more mural nodules. The "target" appearance occurred much less frequently in the small intestine than in the stomach and duodenum. In one case, innumerable melanoma nodules were present that resembled a polyposis syndrome. Seven patients demonstrated a large excavating mass in the mid or distal small bowel. In four cases, the entire mass was ulcerated. Angiography revealed a variety of vascular patterns of liver metastases; these ranged from hypervascular to totally hypovascular. Involvement of biliary ducts and pancreatic area was demonstrated primarily by percutaneous transhepatic cholangiography when jaundice was present. Biliary obstruction occurred in the porta hepatis region as well as at the distal common bile duct by peripancreatic nodes. Mesenteric masses were often purely extrinsic, causing impression upon and displacement of bowel loops. Because of extended survival due to improved chemotherapy and immunotherapy, the importance of careful radiologic examination of the melanoma patient is stressed.

1091 GRAY SCALE ULTRASONOGRAPHY OF CALCIFIED LIVER METASTASES.

(Eng.) Katragadda, C. S.; Goldstein, H. M.; Green, B. (M. D. Anderson Hosp. and Tumor Inst., Houston, TX 77030). *Am. J. Roentgenol.* 129(4):591-593; 1977.

Three cases of calcified liver metastases demonstrating acoustical shadowing on gray scale ultrasonography are reported. The patients had metastases from adenocarcinomas of the rectosigmoid, cecum, and splenic flexure, resp. Plain abdominal radiographs demonstrated the calcifications, but they were not readily apparent in most cases. It is possible that gray scale ultrasonography will disclose calcified metastases in a patient with a false-negative radiograph.

1092 ULTRASONIC SCANNING FOR FOCAL LIVER LESIONS.

(Eng.) Rasmussen, S. N.; Bagger, J.; Wagner, F.; Pedersen, J. F.: Kristensen, J. K. (Blegdamshospitalet, Blegdamsvej 3, DK-2200 Copenhagen N, Denmark). *Dan. Med. Bull.* 24(4): 151-153; 1977.

The diagnostic accuracy of ultrasonic bistable scanning for focal liver lesions was evaluated in 157 patients. Using the information from the patients' charts up to the date of the ultrasonic examination, these 157 cases were divided into two categories: (A) patients strongly suspected of having focal liver lesions and (B) patients only slightly suspected of having focal liver lesions. In group A the predictive values of positive (lesion present) and negative (no lesion present) ultrasonic findings were 81% (62-94%) and 33% (10-65%), resp., with 95% confidence limits in brackets. In group B the corresponding values were 74% (51-90%) and 64% (52-75%), resp. It is concluded that in group A no diagnostic profit was obtained by the ultrasonic examination, while some diagnostic profit was obtained in group B. The diagnostic accuracy increased with an increasing number of focal liver lesions and with increasing size of the lesions.

1093 A COMPARISON OF GRAY SCALE ULTRASOUND AND RADIONUCLIDE IMAGING FOR THE DETECTION OF FOCAL HEPATIC LESIONS: OPEN SHUTTER TECHNIQUE.

(Eng.) Zatz, L. M.; Gouldin, J. A.; Hanley, G. A. (Veterans Admin. Hosp [114], Palo Alto, CA 94304). *J. Clin. Ultrasound* 5(3):178-184; 1977.

The results of a new, previously described, gray scale ultrasound technique were compared with those of radionuclide imaging to determine if the former technique could replace the latter in the detection of focal hepatic lesions. The conventional B scan ultrasound unit was modified by the addition of a specially built logarithmic amplifier and a high resolution nonstorage oscilloscope. One hundred and five consecutive patients submitted for radionuclide imaging of the liver were examined with ultrasound using a standardized scanning system. The ultrasound technique produced scans that were technically poor or inadequate in 37% of the patients studied. In the studies in which there has been confirmation, the ultrasound diagnosis was accurate in 73% and the radionuclide diagnosis was correct in 83%. The combined accuracy of the two studies was 93%. In 11 patients, ultrasound more clearly defined the lesion that were demonstrated by both techniques or demonstrated the nature of suspicious or equivocal areas on the radionuclide images. In 48 patients, the radionuclide scan imaged the liver more completely or demonstrated lesions more clearly than did the ultrasound examination. This specific approach to ultrasound gray scale imaging appears to be a valuable supplemental tool to radionuclide imaging, but at its present stage of development, cannot replace it as a routine screening technique for hepatic disease.

1094 THE INTERPRETATION OF THE RADIONUCLIDE SUBTRACTION SCAN IN PANCREATIC CARCINOMA.

(Eng.) Andrews, J. T.; Kidd, G.; Steven, L. W.; McKay, W. J.; Lichtenstein, M. (Royal Melbourne Hosp., Melbourne, Australia). *Australas. Radiol.* 21(1):53-59; 1977.

An attempt was made to indicate the different types of radionuclide subtraction scan patterns that can occur in pancreatic carcinoma. Forty-four consecutive patients with established clinical or proven histological diagnosis of carcinoma of the pancreas were followed from a total series of 800 who presented for radionuclide subtraction scanning. Over one-third of the patients studied presented with ^{75}Se-selenomethionine uptake in the tumor region. The tumor was diagnosed because of the presence of a filling defect in an otherwise normal pancreatic scan in only four cases. Despite the differing scan presentations of pancreatic carcinoma, it was generally not possible to differentiate a benign from a malignant lesion on the basis of the scan results alone.

1095 OPERATIVE CHOLANGIOGRAPHY. NEW CHOLANGIOGRAM CATHETER CLAMP AND IMPROVED TECHNIQUE. (Eng.) Borge, J. (Queen of the Valley Hosp., 980 Traneas St., Napa, CA 94558). *Arch. Surg.* 112(3): 340-342; 1977.

Experience with 225 cases of routine operative cholangiography, utilizing a new squeeze-locking, split-loop clamp to secure the catheter inside the cystic duct plus an x-ray film technique using two different dye concentrations is presented. No surgical or procedural difficulty was experienced in any of the 225 cases. Additional operating time for the procedure averaged under 5 min, with only one inconclusive x-ray film study. These results suggest that the new catheter clamp and the two-film technique provide a mechanical simplification of the procedure and that many of the causes of inconclusive x-ray film study have been eliminated.

1096 AN IMPROVED METHOD OF EXAMINING THE STOMACH BY THIN-COATING DOUBLE-CONTRAST TECHNIQUE. (Ger.) Tenner, R.; Kurosawa, A. (Tinsdaler Weg 21, 2000 Wedel/Holst., W. Germany). *Fortschr. Geb. Roentgenstr. Nuklearmed.* 125(6): 490-496; 1976.

GASTROINTESTINAL DISEASES

ESOPHAGUS

1146 INTRODUCTION OF A PNEUMATIC DILATOR WITH THE HELP OF A GASTROSCOPE IN ACHALASIA--A NEW, NONTRAUMATIC TECHNIC.

(Eng.) Singal, S. K.; Barfi, R.; Hossain, T. Z. (Allen Park Veterans Admin. Hosp., Detroit, MI). *Am. J. Gastroenterol.* 67(5):494-496; 1977.

A new endoscopic technique to introduce a pneumatic dilator through the lower esophageal sphincter is described in a patient with achalasia. The patient, a 96-yr-old man, was found to have a markedly dilated esophagus with a narrow distal end. An esophageal motility study showed no peristaltic response to swallowing, increased lower esophageal sphincter pressure with no relaxation on swallowing, and a positive response to the urecholine test. A loop of surgical suture (27.5 cm diameter) was tied to the flexible spring-wire tip of a Jackson-Mosher pneumatic dilator before it was passed into the esophagus with the patient lying on his left side. A GIF-K gastroscope was introduced into the esophagus beside the dilator. The loop of silk was identified and caught by biopsy forceps passed through the gastroscope. The forceps were then withdrawn so that their tip lay just inside the end of the biopsy channel. Under direct vision, the gastroscope was passed through the lower esophageal sphincter into the stomach pulling the silk and the dilator along with it. Once the lower end of the pneumatic bag was ascertained to lie below the lower esophageal sphincter area, the biopsy forceps were opened to free the silk loop. The gastroscope was then removed while the pressure was maintained on the stylet to prevent the dilator from being withdrawn. The position of the pneumatic bag was then adjusted fluoroscopically, and a pressure of 6.2 kg/6.5 cm^2 was applied for 2 min. The patient improved markedly after dilatation. This technique can be very useful in patients with achalasia associated with either sigmoid-shaped esophagus or epiphrenic diverticulum where blind introduction of the dilator may not be possible.

1147 LONG-TERM ESOPHAGEAL FUNCTION FOLLOWING REPAIR OF ESOPHAGEAL ATRESIA.

(Eng.) Orringer, M. B.; Kirsh, M. M.; Sloan, H. (C7175 Univ. Hosp., Ann Arbor, MI 48109). *Ann. Surg.* 186(4):436-443; 1977.

The long-term esophageal motor disturbances and incidence of gastroesophageal reflux after surgical repair of esophageal atresia were evaluated in 22 patients postoperatively. The patients were evaluated by personal interview and by esophageal manometry and acid reflux testing. Previous barium swallow examinations had demonstrated varying degrees of anastomotic narrowing (12 patients), abnormal esophageal motor function (11), gastroesophageal reflux (2), and hiatal hernia (1). Ten patients experienced intermittent dysphagia for solid foods. Seven had typical symptoms of gastroesophageal reflux. Esophageal function tests, including manometry and intraesophageal pH recording, demonstrated varying abnormalities of esophageal motility in 21 patients and moderate to severe gastroesophageal reflux in 13. Two patients required reconstruction of the esophagogastric junction for control of severe reflux esophagitis. The unexpected high incidence of gastroesophageal reflux in these patients, coupled with abnormal esophageal motility that impairs normal acid clearing, renders them more prone to reflux esophagitis. Careful long-term evaluation for gastroesophageal reflux and its complications is indicated following primary repair of esophageal atresia. Evaluation of esophageal function with intraesophageal pressure and pH recordings is a far more sensitive indicator of esophageal physiology than the barium swallow examination.

1148 ROLE OF LOWER ESOPHAGEAL SPHINCTER INCOMPETENCE IN RECURRENT PNEUMONIA AFTER REPAIR OF ESOPHAGEAL ATRESIA.

(Eng.) Whitington, P. F.; Shermeta, D. W.; Seto, D. S. Y.; Jones, L.; Hendrix, T. R. (Univ. Wisconsin Sch. Medicine, Madison, WI 53706). *J. Pediatr.* 91(4):550-554; 1977.

To define the etiology of recurrent aspiration pneumonitis after the successful repair of esophageal atresia (EA), esophageal manometry was performed in eight patients (aged 11 weeks to 20 yr) who had undergone repair of EA and tracheoesophageal fistula. Two patients who had had recurrent pneumonia had subnormal lower esophageal sphincter pressure; they also had a history of severe regurgitation, and a barium esophagram demonstrated free gastroesophageal reflux. The lower esophageal sphincter incompetence in these patients was apparently corrected by the administration of bethanechol. These studies show that recurrent pneumonitis after repair of EA is often due to an incompetent lower esophageal sphincter with reflux and aspiration.

1149 PHARMACOTHERAPY OF AN ULCER IN BARRETT'S ESOPHAGUS: CARBENOXALONE AND CIMETIDINE.

(Eng.) Thompson, W. G.; Barr, R. (Ottawa Civic Hosp., 1053 Carling Ave., Ottawa, Ontario K1Y 4E9, Canada). *Gastroenterology* 73(4):808-810; 1977.

The case of a 70-yr-old man who had specialized columnar epithelium in the esophagus up to the upper esophageal sphincter, 19 cm from the incisor teeth, is presented. The patient had a small sliding hiatal hernia, but the lower esophageal sphincter was located at 39-41 cm. Above the sphincter, the patient had large peptic ulcers that failed to heal after 1 yr of a conventional antireflux regimen. Carbenoxalone sodium (50 or 100 mg, t.i.d.) led to healing in 3 months. However, the ulcers recurred after discontinuation of the drug. On a second attempt, carbenoxalone effected modest healing, but was stopped because of hypertension and hypokalemia. Cimetidine therapy (300 mg, t.i.d. and 600 mg at bedtime) led to complete healing of the ulcer within a month. The authors conclude that both carbenoxalone and cimetidine are useful in the treatment of an ulcer in Barrett's esophagus. However, cimetidine may be more rapidly effective and does not produce dangerous side-effects.

1150 MANAGEMENT OF COMPLICATIONS OF FUNDOPLICATION AND BARRETT'S ESOPHAGUS.

(Eng.) Burnett, H. F.; Read, R. C.; Morris, W. D.; Campbell G. S. (Veterans Admin. Hosp., 300 E. Roosevelt Rd., Little Rock, AR 72206). *Surgery* 82(4):521-530; 1977.

Experience with patients requiring reoperation for complications of fundoplication and with the management of columnar-lined distal esophagus (Barrett's) is reviewed. Fifteen patients required reoperation for gastric fistula (6), progressive esophagitis/stricture (4), obstruction by the wrap (3), carcinoma (1), failed pericardioesophagoplasty (1), and gastric ulcer (1). Of the six patients with gastric fistulas, five had transthoracic Nissen procedures, and three died without surgical closure having been attempted. One survived after operative closure, and two survived after esophageal exclusion. Progressive esophagitis/stricture followed abdominal Nissen operations in two patients, Belsey procedure (1 case), and Belsey with Collis gastroplasty (1 case). Remedial thoracic Nissen operations gave good results in two patients. Esophageal obstruction by the wrap in three patients was managed by resection and distal colon interposition, with good results. Those with cancer, a failed pericardio-esophagogastrectomy, Woodward procedure, and wedge resection, resp., and all are doing well. Eight patients had Barrett's esophagus, one of whom had an associated cancer. Fundoplication gave good results in three of five patients; there was one death from gastric fistula. Failed operations on the gastroesophageal junction can be rendered by carefully selected surgical techniques based on a thorough preoperative evaluation of the patient. Barrett's esophagus is managed successfully with fundoplication and dilatation. There is an increased incidence of cancer in this disorder, which demands long-term follow-up.

1151 EXPERIENCE IN THE MANAGEMENT OF ACUTE ESOPHAGEAL BURN.

(Ger.) Muller, H. (Ful-, Orr-, Es Bronchologiai Osztaly, Magyei Korhaz, 6601 Szentes, Hungary). *HNO* 25(5):168-171; 1977.

The treatment of 151 patients with acute esophageal burns caused by corrosive substances is described. The patients included 4 2- to 4-yr-old children, and 23 patients in severe, critical condition. Pain relief, administration of atropine and pipolphenin injection are necessary at first, but gastric lavage is not performed, and the poison is not neutralized. The principal treatment consists of cortisone administration and mechanical dilatation of the esophagus to prevent the formation of granulation tissue and esophageal stricture. Blind bougienage is contraindicated because of its inherent hazards. Cortisone is administered to adults in daily doses of 200-400 mg, and the dose is reduced by 50-100 mg after 5-8 days. Children (up to age 10) receive 100-200 mg/day, depending on age. After cessation of dysphagia, cortisone is replaced by prednisolone, which is given in daily doses of 20-30 mg for maintenance. Antibiotic therapy with penicillin (3-5 million U for adults) is absolutely necessary during cortisone therapy. All patients with slight to medium degree burns were healed by cortisone therapy, but 6 of the 23 patients with severe burns died (5 from uncontrollable bleeding, 1 from perforation of the trachea). Gastric perforation and gastric ulcer as complications of cortisone treatment were not observed. The findings indicate that cortisone is of great value in the treatment of severe esophageal burns.

1152 THE ROLES OF ESOPHAGOSCOPY VS. RADIOGRAPHY IN DIAGNOSING BENIGN PEPTIC ESOPHAGEAL STRICTURES.

(Eng.) Hiatt, G. A. (Fronk Clinic, 839 South Beretania St., Honolulu, Hawaii 96813). *Gastrointest. Endosc.* 23(4):194-195; 1977.

The correlation between endoscopic and radiographic diagnosis of benign peptic esophageal stricture was studied retrospectively in 52 patients found to have significant strictures at esophagoscopy. Radiographs read as positive for stricture ranged from 40% to 34.1% when taken 1-8 months before endoscopy. None of 10 patients who had a barium swallow after the endoscopic diagnosis was reported as having a stricture. These data indicate that radiography is not entirely reliable in the diagnosis of benign peptic esophageal strictures and that esophagoscopy should be routinely employed when dysphagia is a symptom.

1153 REMARKABLY LARGE, BENIGN ESOPHAGEAL TUMOR. DIFFICULTIES IN DIAGNOSIS.

(Eng.) Orchard, J. L.; Peternel, W. W.; Arena, S. (Mercy Hosp., Pittsburgh, PA 15219). *Am. J. Dig. Dis.* 22(3):266-269; 1977.

The case of a patient with a leiomyoma of the esophagus is reported because the tumor reached extraordinary size before becoming symptomatic and caused some difficulty in diagnosis despite its large size. The diagnosis was made with the fiberoptic esophagoscope after standard roentgenograms and rigid esophagoscopy were inconclusive. The tumor was removed through a cervical incision. Attention is called to the potential fatal outcome of these lesions.

1154 ESOPHAGEAL ULCERS IN IMMUNODEFICIENCY WITH ELEVATED LEVELS OF IgM AND NEUTROPENIA.

(Eng.) Vanderhoff, J. A.; Rich, K. C.; Stiehm, E. R.; Ament, M. E. (Dept. Pediatrics, MDCC 22-442 UCLA, Center Health Sciences, Los Angeles, CA 90024). *Am. J. Dis. Child.* 131(5):551-552; 1977.

The case of a 17-yr-old boy with immunodeficiency, elevated levels of immunoglobulin M, and neutropenia who developed distal esophageal ulcers and stricture is presented. Although his lower esophageal sphincter pressure was decreased, he had normal acid reflux test results, normal findings from acid clearing studies, and absence of diffuse esophagitis at esophagoscopy. Neutropenia and hypogammaglobulinemia are postulated to be pathogenic factors in his esophageal ulcers.

STOMACH

1175 CARBOHYDRATE CONTENT OF ENDOSCOPIC GASTRIC BIOPSIES IN CARCINOMA OF THE STOMACH. (Eng.) Machado, G.; Clamp, J. R.; Read, A. E. (Bristol Royal Infirmary, Bristol, England). *Gut* 18(8):670-672; 1977.

Mucous glycoproteins were studied in gastric biopsies of 37 normal controls and in the cancerous and normal biopsies of 27 patients with gastric carcinoma. There were statistically significant ($p<0.001$) changes in mannose and *N*-acetylgalactosamine levels in normal and carcinomatous stomachs in both secretors and nonsecretors. The mean mannose level in the 25 normal secretors was 1.0 (residue of mannose relative to a galactose content of 6.0 residues). Among the 12 cancer patients who were secretors, the mean mannose levels in the cancerous and noncancerous areas were 1.7 and 1.5, resp. In the nonsecretors, the corresponding mannose contents were 1.3, 2.2, and 2.0, resp. The levels of *N*-acetylgalactosamine in the secretors were 4.0, 2.6, and 2.8, resp., while in the nonsecretors they were 3.8, 2.2, and 2.6, resp. These studies show that there is a significant increase in mannose content and a significant decrease in *N*-acetylgalactosamine in the gastric mucus of patients with gastric cancer, in comparison with the levels in normal subjects. The fact that both the cancerous and noncancerous areas of cancer-bearing stomach show carbohydrate changes suggests a change in the relative amounts of these two fractions and therefore a corresponding change in the cells giving rise to them. Carbohydrate analysis of adherent gastric mucus could be useful in detecting susceptibility to gastric cancer.

1176 OUTCOME OF GASTRIC CARCINOMA DETECTED BY GASTRIC MASS SURVEY IN JAPAN. (Eng.) Kaneko, E.; Nakamura, T.; Umeda, N.; Fujino, M.; Niwa, H. (Sch. Medicine, Hamamatsu Univ., Hamamatsu Japan). *Gut* 18(8):626-630; 1977.

To determine the value of the gastrocamera in mass screening for gastric carcinoma, the results of six selected mass survey groups consisting of 90,557 subjects were studied. One hundred thirty seven cases of gastric carcinoma were detected and followed up postoperatively for up to 16 yr. They consisted of 55 cases of early and 74 cases of advanced carcinoma; the stage of malignancy was unknown in the remaining cases. The relative 5-yr and 10-yr survival rates in the 137 cases were 0.628 and 0.642, resp., and those for early carcinoma were 0.959 and 1.016, resp. These rates are remarkably high. The 5-yr survival rate in those who were followed up after operation for more than 5 yr (83 cases) was 0.554, which is much higher than that of outpatients who presented only after developing symptoms. The use of the gastrocamera markedly improved the detection rate of gastric carcinoma in mass screening programs.

1177 CELL-MEDIATED IMMUNITY IN PATIENTS WITH GASTRIC CARCINOMA: CORRELATION BETWEEN CLINICAL STAGE AND IMMUNOCOMPETENCE. (Eng.) Branco, P. D.; Raia, A. A.; Varella, A. D.; Kopersztich, S.; Abrao, S.; Nakaie, M.; Castro, J. P. (Facultade de Medicina, Universidade de Sao Paulo, Sao Paulo, Brazil). *Chir. Gastroenterol.* 11(2): 187-191; 1977.

To determine whether defective cell-mediated immunity (CMI) can predispose to the establishment and progression of neoplasms, CMI was investigated in 75 patients who had undergone surgery for gastric carcinomas. The 2,4-dinitrochlorobenzene (DNCB) sensitization test was used as an index of CMI. The patients were divided into three groups according to the stage of the tumor: patients with localized and resectable tumors (LD); patients with disseminated tumors, but with the progression of the disease restricted to the regional lymph nodes (DD), in whom it was possible to achieve some surgical procedure; and patients with metastatic disease with great extension of the primary disease and with widespread metastasis (MD). In the 27 patients with LD, 17 negative and 10 positive DNCB reactions (62.96% and 37.04%, resp.) were observed. In 26 patients with DD, 17 negative (65.38%) and 9 positive reactions (34.62%) were seen. In 22 patients with MD, 20 negative (90.9%) and 2 positive reactions (9.1%) were observed. During a 6-month follow-up, 20 DNCB-negative patients died, while only 4 DNCB-positive patients died. The results demonstrate a marked difference in CMI between patients with MD, DD, and LD.

1178 GASTRIC MUCOSAL BIOPSY IN EOSINOPHILIC (ALLERGIC) GASTROENTERITIS. (Eng.) Katz, A. J.; Goldman, H.; Grand, R. J. (Children's Hosp. Medical Center, Boston, MA 02115). *Gastroenterology* 73(4):705-709; 1977.

Six patients were studied to assess the value of gastric mucosal biopsy in establishing the diagnosis of eosinophilic (allergic) gastroenteritis. The gastric mucosa was abnormal in all cases, revealing marked eosinophilic infiltration and necrosis and regeneration of the epithelial cells. A single gastric biopsy was diagnostic in all six cases and provided the primary diagnosis in three. Intestinal biopsies varied considerably in appearance even in the same patient, ranging from normal to villous shortening and crypt hyperplasia with epithelial cell necrosis. Other patients with peripheral eosinophilia alone or intestinal disease of other etiologies had normal gastric biopsies. Gastric mucosal biopsy appears to be valuable in the diagnosis of eosinophilic gastroenteritis and should be routinely obtained. The gastric lesion may contribute to the protein loss, gastrointestinal bleeding, and iron-deficiency anemia observed in this condition.

1179 HEMOLYTIC SUBSTANCES IN THE GASTRIC CONTENTS: FREQUENCY OF LYSOLECITHIN DETECTION. (Ger.) Clemencon, G.; Burgi, W. (Kantonsspital Olten, CH-4600 Olten, Switzerland). *Schweiz. Med. Wochenschr.* 107(27):952-956; 1977.

Samples of gastric contents were taken from 152 patients with gastroduodenal reflux after an overnight fast and examined for hemolytic activity and lysolecithin content. The hemolysis tests were positive in 97/152 cases: in 13/29 patients with normal mucosa, in 13/20 patients with reflux esophagitis, in 33/49 patients with gastric ulcer, in 10/12 patients with gastric erosion, in 15/25 patients with superficial gastritis, and in 13/17 patients with chronic atrophic gastritis with intestinal metaplasia. Eighty-eight of the positive samples were analyzed by thin-layer chromatography for lysolecithin content. Lysolecithin was not found in nine samples. The lysolecithin levels averaged 41.5 mg/100 ml in 13 patients with normal gastric mucosa, 28.5 mg/100 ml in 9 patients with reflux esophagitis, 19.7 mg/100 ml in 26 patients with gastric ulcer, 38.4 mg/100 ml in 8 patients with gastric erosion, 61.3 mg/100 ml in 13 patients with superficial gastritis, and 43.6 mg/100 ml in 10 patients with chronic atrophic gastritis with intestinal metaplasia. The lysolecithin levels found in patients without gastroduodenal reflux in previous investigations averaged 0.9 mg/100 ml. The pH value of the gastric contents, ranged from 1.1 to 7.8 and did not correlate with the lysolecithin level or the result of the hemolysis test, nor was there any correlation between the lysolecithin level and bilirubin level. Along with data in the literature, these findings indicate that lysolecithin may exert a pathogenic effect in the development of various gastric lesions.

1180 LOCATION OF ULCER IN THE STOMACH AND PYLOROANTRAL HYPERTROPHY: CORRELATION BETWEEN THE SITE OF ULCER AND GASTRIC WALL HYPERTROPHY IN GASTRIC ULCER. (Ger.) Liebermann-Meffert, D.; Allgower, M. (Chirurg. Dept., Kantonsspital Basel, CH-4004 Basel, Switzerland). *Z. Gastroenterol.* 14(6):613-619; 1976.

Relationships between the localization of gastric ulcer and hypertrophy of the pyloroantral wall (musculature + submucosa + mucosa) were studied in a random series of 77 resected specimens with solitary (60) and multiple (40) gastric ulcers. Sixty-three ulcers were localized to the lesser curvature, 29 to the posterior wall, 6 to the anterior wall, and 2 to the greater curvature. No difference was found between solitary and multiple ulcers in terms of their localization, but ulcers localized to the posterior wall were more frequent in men than in women. Most of the 100 ulcers were at distances of up to 90 mm from the pylorus. The distance between solitary ulcers and the pylorus was usually 20-60 mm, that between multiple ulcers and the pylorus, 0-40 mm. The distance was about 60 mm in most cases, with some difference between men and women in this respect. No significant correlation was found between the distance of solitary and multiple ulcers from the pylorus and the hypertrophy of the entire pyloroantral wall, but the musculature was significantly less hypertrophied in the case of solitary ulcers further from the pylorus, and significantly more hypertrophied in the case of multiple ulcers further from the pylorus compared to the cases of ulcers closer to the pylorus ($p<0.02$).

STOMACH

Peptic Ulcers

1201 PERFORATION OF CHRONIC PEPTIC ULCERS AFTER CIMETIDINE. (Eng.) Wallace, W. A.; Orr, C. M. E.; Bearn, A. R. (Queen Elizabeth Hosp., Sheriff Hill, Gateshead NE9 6SX, England). *Br. Med. J.* 2(6091):865-866; 1977.

Three cases of chronic peptic ulcer perforation in which abrupt cessation of cimetidine treatment may have been the cause are reported. Perforation of a duodenal ulcer in the first patient occurred 5 days after he had completed a 6-week course of cimetidine (200 mg thrice daily plus 400 mg at night). The second patient's perforation occurred 10 days after he had completed a 4-week course of cimetidine (200 mg thrice daily plus 400 mg at night) for gastric ulcer, and perforation in the third patient occurred 10 days after she had completed a 6-week course (same dose regimen) for duodenal ulcer. The treatment resulted in relief of symptoms in the two patients with duodenal ulcer but not in the patient with gastric ulcer. All three patients were prescribed cimetidine by their general practitioners and had no pretreatment investigation and no subsequent investigation planned to confirm ulcer healing; the possibility that gastric cancer was present was therefore not excluded. In all patients, the large size of the perforation resulted in moderate to gross contamination of the peritoneal cavity, which precluded definitive ulcer surgery in two patients. The perforations may have occurred because of rebound hyperacidity after cimetidine had been stopped or because the partially healed chronic ulcer, which had responded to cimetidine, may have been less resistant to perforation when exposed to the normal acid concentrations after cimetidine had been stopped.

SMALL INTESTINE

1223 INFLUENCE OF SMALL INTESTINAL SHUNT AND SMALL INTESTINAL RESECTION ON GASTRIN RELEASE. (Ger.) Wedell, J.; Fritsch, W. P.; Hausamen, T. U. (Chirurg. Abteilung, Kreiskrankenhauses Herford, 4900 Herford, W. Germany). *Z. Gastroenterol.* 14(6):620-625; 1976.

Gastric acid secretion and serum gastrin levels were studied in 10 normal subjects with normal body weight (group 1), in 7 patients who had undergone jejunoileal bypass surgery for excessive obesity 14 months earlier (group 2), and in 3 patients (group 3) who had undergone subtotal small intestinal resection for infarction 1-36 months earlier. Normal gastric acid secretion was found in groups 1 and 2, and the secretion was at the lower limit of the normal range in group 3. There was no significant difference in the fasting serum gastrin levels between groups 1 and 2, but significantly increased fasting serum gastrin levels were found in group 3. Increase in the serum gastrin level was seen in group 1 during the first 2 hr following the administration of a test meal (100 g of homogenized, low-fat raw meat), but no significant change was seen in group 2 (the serum gastrin level showed no change in 3 patients, and marked gastrin release was seen in the other 4). The serum gastrin level was significantly higher in group 3 than it was in group 1 ($p<0.0005$). The hypergastrinemia seen in group 3 after the test meal may be due to the reduced breakdown of gastrin.

SMALL INTESTINE

Malabsorption

1261 IMMUNOGLOBULINS IN JEJUNAL MUCOSA AND SERUM FROM PATIENTS WITH ADULT COELIAC DISEASE. (Eng.) Baklien, K.; Brandtzaeg, P.; Fausa, O. (Rikshospitalet, Oslo 1, Norway). *Scand. J. Gastroenterol.* 12(2):149-159; 1977.

Ig-containing cells were quantitated immunohistochemically in biopsy specimens from the proximal jejunal mucosa of controls and patients with celiac disease (CD). The numbers of IgA, IgM, and IgG immunocytes in a defined "mucosal tissue unit" were, on the average, raised 2.4, 4.6, and 6.5 times, resp., when 13 adult patients with untreated CD were compared with 15 patients who had a histologically normal mucosa. The IgA:IgM:IgG cell ratios averaged 66:28:6 in untreated CD and 79:18:2.6 in the controls. Similar quantitative data in 10 patients with treated CD were intermediate. IgD- and IgE-containing cells were rare in all patient groups. Most patients in a heterogeneous malabsorption group showed a jejunal Ig-containing cell population similar to that seen in CD, indicating that the local immunocyte pattern may not be specific for the latter disease. The only significant alteration in serum Ig levels related to CD was a raised concentration of IgA compared with normal. This was consistent with the increased amounts of extracellular IgA revealed in the mucosa. However, there was no indication of a defect in the transport of dimeric IgA and IgM through secretory component-producing cells, which in the CD mucosa were present in both crypt and surface epithelium.

1262 IgA CLASS RETICULIN ANTIBODIES IN RELATIVES OF PATIENTS WITH COELIAC DISEASE. (Eng.)

Mallas, E. G.; Williamson, N.; Cooper, B. T.; Cooke, W. T. (General Hosp., Birmingham, England). *Gut* 18(8):647-650; 1977.

Patients with various gastrointestinal diseases, patients with celiac disease, and relatives of patients with celiac disease were investigated for IgA class reticulin antibodies, using monospecific anti-IgA and IgG antisera. IgA class reticulin antibodies were not found in any of 19 patients with Crohn's disease, 22 with ulcerative colitis, or 19 with hiatal hernia despite a significant incidence of IgG class reticulin antibodies. None of 56 normal healthy subjects was positive. In contrast, 13 (76%) of the sera from 17 patients with celiac disease on normal diet were positive for IgA class antibodies as were 19 (20%) of 93 first-degree relatives. Seventy-three relatives underwent jejunal biopsy. Grade III (flat) histology was found in 13 and, of these patients, 10 (77%) showed IgA class reticulin antibody in their serum. Determination of IgA class reticulin antibodies is a useful test to determine which relative must be biopsied.

1263 COELIAC DISEASE: THE ABOLITION OF GLIADIN TOXICITY BY ENZYMES FROM Aspergillus niger. (Eng.)

Phelan, J. J.; Stevens, F. M.; McNicholl, B.; Fottrell, P. F.; McCarthy, C. F. (Dept. Biochemistry, Univ. Coll., Galway, Ireland). *Clin. Sci. Mol. Med.* 53(1):35-43; 1977.

Xylose absorption, mucosal morphology, and brush border enzymes were studied in patients with celiac disease who ingested carbohydrate-free gliadin, to determine whether the toxicity of gliadin in these patients involves its carbohydrate components. Carbohydrate was removed from dialyzed gliadin by dissolving 50 g in acetic acid, adjusting the pH to 4.5, and adding a mixture of carbohydrases prepared from *Aspergillus niger*. Proteolytic activity was negligible. The gliadin was dialyzed, freeze-dried, and baked into 450-g loaves of bread with gluten-free flour. Three patients in remission each received five loaves of this bread, while a fourth received bread containing untreated gliadin. Only this latter patient showed a definite impairment in xylose absorption. The small intestinal morphology, including villus height, crypt depth, epithelial cell height, and the presence or absence of inflammatory cells in the epithelium and lamina propria, showed no change in the three patients who received enzyme-treated gliadin, while the epithelial cell height and the number of intraepithelial lymphocytes decreased and increased, resp., in the patient who received untreated gliadin. Only this patient showed decreases in all enzymes studied (alkaline phosphatase, lactase, and sucrase). The patient receiving untreated gliadin also had diarrhea, whereas the other three patients did not. The results suggest that carbohydrases present in the microbial extract of *A. niger* are responsible for detoxifying gliadin; however, until a complete characterization of the enzymes involved has been made, the possibility remains that a side-chain substituent other than carbohydrate may account for the toxicity of gliadin.

1264 ACTIVATION OF THE ALTERNATIVE PATHWAY BY GLUTEN: A POSSIBLE AETIOLOGICAL FACTOR IN DERMATITIS HERPETIFORMIS. (Eng.)

Massey, A.; Capner, P. M.; Mowbray, J. F. (St. Mary's Hosp. Medical Sch., London, England). *Immunology* 33(3): 339-342; 1977.

Experiments were carried out to determine whether direct activation of the alternative pathway of complement (c) by gluten in the serum is involved in the etiology of dermatitis herpetiformis and celiac disease lesions subsequent to gluten-induced jejunal damage. C3, factor B, and their respective breakdown products were measured by a two-way, antigen-antibody crossed immunoelectrophoresis. In normal serum, there was usually a low level of "spontaneous" C3 conversion. This background level was higher in sera with normal, than in those with reduced, factor B activity. The background was abolished by the presence of EDTA in the incubation mixture. The addition of gluten fractions to normal serum was shown to activate the alternative pathway of complement. C3 and factor B breakdown occurred in a manner analogous to that when activated by zymosan, in the presence of MgEGTA and in serum devoid of classical pathway activity. Bypass activation may be the primary event when gluten enters the serum across a damaged gut mucosa. Immune complexes containing noncomplement-fixing IgA antigluten antibody are carried to the skin, where it is proposed that complexed gluten activates C3 and initiates an inflammatory reaction.

LARGE INTESTINE

1276 CHANGES IN SITE DISTRIBUTION OF COLORECTAL CARCINOMA IN CONNECTICUT, 1940-1973. (Eng.) Snyder, D. N.; Heston, J. F.; Meigs, J. W.; Flannery, J. T. (Connecticut Cancer Epidemiology Unit, 30 College St., New Haven, CT 06510). *Am. J. Dig. Dis.* 22(9):791-797; 1977.

Because the proportion of colorectal cancer occurring above the rectosigmoid junction has been increasing over time, the 40,771 cases of colorectal carcinoma reported to the Connecticut Tumor Registry from 1940 through 1973 were analyzed to determine the incidence in the ascending, transverse, descending, and sigmoid colon, and the rectum. The number of cases, the proportion of cases, and incidence rates of cancer in the ascending colon and sigmoid have increased over the 34 yr. The percentage of cases of ascending colon carcinoma between 1940 and 1944 was 13.4%, whereas that between 1970 and 1973 was 21.8%. The increases were greatest among people over 65 yr old. Only about half of colorectal cancer can now be identified with the rigid, 25-cm sigmoidoscope. Other tests must be used for early diagnosis of the increased number of cancers in the upper parts of the colon.

1277 MYOTOMY: SURGICAL TREATMENT OF DIVERTICULITIS. (Ger.) Kyrle, P. (Chirurgische Abteilung, Krankenanstalt Rudolfstiftung, Wahringerstr. 27, A 1090 Vienna IX, Austria). *Zentralbl. Chir.* 102(17):1040-1044; 1977.

Sigmoid myotomy was performed in 36 patients with sigmoid diverticulosis (18 cases) and sigmoid diverticulitis (18 cases). About half of the patients had concurrent diseases, such as diabetes mellitus, cardiovascular diseases with hypotension or hypertension, disorders in peripheral arterial circulation, cholecystitis, and sciatica. The original Reilly operation (transection of the tenia libera of the sigmoid colon to the mucosa) was performed in 34 cases and Hodgson's myotomy (alternating incisions in the tenia libera) in 2 cases. Severe intraoperative and postoperative complications were seen in six cases, including perforation of the mucosa, fistulization, and stenosis of the sigmoid colon. The postoperative mortality was 4/36, due to peritonitis (2), pulmonary embolism (1), and acute pancreatitis (1). The surgical results were good in 29 cases, unsatisfactory in 2, and another patient died of late complications. Exteriorization is recommended in the case of widespread inflammation that makes the separation of the layers of the intestinal wall difficult and increases the risk of mucosal perforation followed by peritonitis. Early carcinoma developing between the diverticula may remain undetected during myotomy, and therefore double-contrast x-ray examination, sigmoidoscopy, and colonoscopy are recommended.

1278 PSEUDOMEMBRANOUS ENTEROCOLITIS IN CHILDHOOD.

(Eng.) Buts, J. P.; Weber, A. M.; Roy, C. C.; Morin, C. L. (Hopital Ste-Justine, 3175, Ste-Catherine Rd., Montreal, Quebec H3T 1C5, Canada). *Gastroenterology* 73(14, Part 1):823-827; 1977.

The clinical, laboratory, and histologic features in five children (5-12 yr) with pseudomembranous enterocolitis are presented. The clinical syndrome, characterized by the acute onset of profuse diarrhea, occurred postoperatively in two patients. All patients had received or were taking antibiotics (penicillin, ampicillin, clindamycin). The disease was severe in four children, who presented with hypoproteinemia. Related complications were edema, ascites, pleural effusion, septicemia, and/or shock. The diagnosis was made on the basis of typical rectosigmoidoscopic findings. Despite intensive therapy (i.v. steroids, nafcillin, and gentamicin; plasma infusions; parenteral alimentation), two children died. The use of parenteral nutrition is advocated in severe cases with exudative enteropathy. When profuse diarrhea occurs postoperatively or does not rapidly subside with discontinuation of antibiotic therapy, a high index of suspicion should be maintained, even in children, for the possibility of pseudomembranous enterocolitis. An emergency rectosigmoidoscopy should be done to make an early diagnosis.

1279 DYSTROPHIC EPIDERMOLYSIS BULLOSA. INTERESTING GASTRO-INTESTINAL MANIFESTATIONS.

(Eng.) Sehgal, V. N.; Rege, V. L.; Ghosh, S. K.; Kamat, S. M. (Goa Medical Coll., Panaji 403 001, Goa, India). *Br. J. Dermatol.* 96(4):389-392; 1977.

The case of a 20-yr-old woman with a long-standing case of dystrophic epidermolysis bullosa in whom gastrointestinal manifestations occurred is presented. Involvement of the large intestine was characterized by recurrent episodes of diarrhea synchronizing with exacerbation of the skin lesions. The radiological investigations revealed two narrow segments, one each in the descending and transverse colon, with ulcer craters in the lower part of the former. The haustra from the distal half of the transverse colon to the sigmoid colon were lost.

1280 INTERNAL SPHINCTER AND THE NATURE OF HAEMORRHOIDS.

(Eng.) Hancock, B. D. (Wythenshawe Hosp., Manchester, England). *Gut* 18(8):651-655; 1977.

To investigate the relationship between an overactive internal anal sphincter and the symptoms of hemorrhoids, internal anal sphincter activity was studied in 84 patients with hemorrhoids and 40 controls without anorectal symptoms. Activity was estimated by measuring maximum resting anal pressure with a water-filled anal balloon probe 7 mm in diameter connected to a strain gauge pressure transducer. There was greater activity of the internal sphincter in patients with hemorrhoids than in controls (107 ± 23.0 versus 85.0 ± 20.5 cm H_2O, $p<0.001$), but there was no significant relation between sphincter activity and duration of symptoms, predominant symptom (bleeding or prolapse), severity of symptoms, history of pain, history of straining at stool, or size of hemorrhoids. Straining at stool occurred significantly more often in patients whose main complaint was prolapse than in those whose main complaint was bleeding ($p<0.025$). Anal dilatation reduced sphincter activity, and the best clinical results were obtained in those with the most active sphincter. An internal sphincter abnormality may be an etiological factor in some patients with hemorrhoids, but there must be other factors as well. Straining at stool may determine whether bleeding or prolapse is the predominant symptom.

1281 METRONIDAZOLE IN THE TREATMENT OF CHRONIC PROCTITIS: A CONTROLLED TRIAL.

(Eng.) Davies, P. S.; Rhodes, J.; Heatley, R. V.; Owen, E. (Univ. Hosp. Wales, Cardiff, Wales.) *Gut* 18(8):680-681; 1977.

The effect of metronidazole treatment was tested in a double-blind controlled study of 22 patients with chronic proctitis. In the crossover study, the patients were given metronidazole suppositories (500 mg, 3 times daily) or a placebo in randomized order during two consecutive 28-day periods. The patients recorded the frequency of daily bowel actions and the occurrence of rectal bleeding, and at the end of each period indicated their assessment of their clinical progress. Of the 18 patients completing the trial, 10 noticed no difference between the two periods, 5 improved on placebo, and 3 improved during the metronidazole period. There were no significant differences in stool frequency, blood loss, the sigmoidoscopic appearance of the rectal mucosa, or histologic changes during the two periods. Metronidazole, given for 28 days, does not appear to benefit patients with proctitis, although initial observations in an open trial had been encouraging.

1282 SPHINCTER DENERVATION IN ANORECTAL INCONTINENCE AND RECTAL PROLAPSE.

(Eng.)

Parks, A. G.; Swash, M.; Urich, H. (St. Mark's Hosp., London, England). *Gut* 18(8):656-665; 1977.

Biopsies of the external anal sphincter, puborectalis, and levator ani muscles were examined in 6 controls, in 24 women and 1 man with long-standing anorectal incontinence (18 of whom also had rectal prolapse), and in 2 men with rectal prolapse alone. In 16 of the women, anorectal incontinence was of unknown cause, but in 8 there was a history of difficult labor. In all the incontinent patients, there was histological evidence of denervation, which was most prominent in the external anal sphincter muscle biopsies, and least prominent in the levator ani muscles. Myopathic features, which were thought to be secondary, were present in the more abnormal biopsies. There were severe histological abnormalities in small nerves supplying the external anal sphincter muscle in the three cases in which material was available for study. Idiopathic anorectal incontinence may be the result of denervation of the muscles of the anorectal sling, and of the anal sphincter mechanism. This denervation could result from entrapment or stretch injury of the pudendal or perineal nerves occurring as a consequence of rectal descent induced during repeated defecation straining, or from injuries to these nerves associated with childbirth.

LARGE INTESTINE

Ulcerative Colitis

1328 EMERGENCY COLECTOMY FOR INFLAMMATORY BOWEL DISEASE. (Eng.) Block, G. E.; Moossa, A. R.; Simonowitz, D.; Hassan, S. Z. (Dept. Surgery, Univ. Chicago, Chicago, IL 60637). *Surgery* 82(4):531-536; 1977.

The results of emergency colectomy for complications of inflammatory bowel disease are described in 53 patients who underwent the operation between 1964 and 1976. All patients were treated consecutively by the authors, on the same surgical service. Thirty-nine patients had ulcerative colitis, 13 Crohn's disease, and 1 pseudomembranous colitis. The indication for operation in 23 patients was hemorrhage; 23 other patients had toxic megacolon, 3 had free perforation, and 4 had fulminant disease. All patients with free perforation or fulminant disease underwent abdominal colectomy; 16 of 23 patients with toxic megacolon received abdominal colectomy, and 7 had proctocolectomy. Seven of 23 patients with hemorrhage underwent proctocolectomy, and 16 underwent abdominal colectomy. The operative mortality rate was 5.6%, and the total mortality rate was 9.4%. The overall mortality rate for the complication of toxic megacolon was 8.7%; following abdominal colectomy, it was 6.1%, and after proctocolectomy, 14.3%. The overall mortality rate for the complication of hemorrhage was 8.7%; following proctocolectomy, it was nil, and after abdominal colectomy, 12.5%. This overall mortality rate compares with the previous decade's mortality rate from the same institutions of 23%. Emergency colectomy is indicated in these patients after prompt and vigorous resuscitative measures and can be performed safely. Proctocolectomy is advocated for those patients whose disease is diagnosed and who suffer massive hemorrhage. Abdominal colectomy is indicated in patients with Crohn's disease with a spared rectum, poor-risk patients with fulminant disease, or patients with toxic megacolon with or without perforation.

1329 ULTRASTRUCTURAL ASPECTS OF COLON EPITHELIUM IN PATIENTS WITH ULCERATED AND GRANULOMATOUS COLITIS. (Ita.) Marinozzi, G.; Familiari, G.; Stillo, F.; Luminari, M.; Giannelli, G. (Istituto di Anatomia Umana Normale dell'Universita di Roma, Rome, Italy). *Minerva Gastroenterol.* 22(4):267-276; 1976.

The epithelium of colonic mucosa was examined by electron microscopy in six patients with ulcerated colitis. Tissue to be examined was obtained by biopsy. Mucosa from patients in the quiescent phase of the disease appeared normal. In patients in the active phase of the disease, the columnar cells were reduced in volume, and interstitial spaces were dilated. Intranuclear inclusion bodies of 400-600 A were seen in all patients. These inclusion bodies may be attributable to herpesvirus. In active cases, round granulomatous bodies of 50-150 A were seen, primarily in the nuclei and occasionally in the nucleoli. Cytoplasmic filaments were also seen in many of the epithelial cells examined. Microfilaments were sometimes noted in the nuclei of cells from patients with active colitis. These filaments are probably the result of mucosal dysplasia.

1330 CLINICAL TRIALS. A LOCAL FOAM AEROSOL IN ULCERATIVE COLITIS. (Eng.) Clark, M. L. (St. Leonard's Hosp., London, England). *Practitioner* 219(1309):103-104; 1977.

The value of 10% hydrocortisone delivered in a foam aerosol in the treatment of distal colitis was examined in 20 patients with ulcerative colitis, Crohn's disease, or nonspecific distal colitis. This treatment was ineffective in three patients; of these, one responded to steroid enemas, while p.o. steroids was necessary in two. Of the 17 patients in whom the foam was effective, 12 had previously received steroid enemas; three of these found the foam enemas more effective than the steroid enemas, while the remainder thought there was no difference between the two treatments. Eleven of the 12 patients who had previously received steroid enemas found that the foam was easier to use. It is concluded that hydrocortisone foam aerosol is a practical and effective form of therapy in cases in which rectal steroids are indicated.

1331 C3 METABOLISM IN ULCERATIVE COLITIS AND CROHN'S DISEASE. (Eng.) Hodgson, H. J. F.; Potter, B. J.; Jewell, D. P. (Massachusetts General Hosp., Boston, MA). *Clin. Exp. Immunol.* 28(3):490-495; 1977.

The metabolism of the third component of complement (C3) was studied in four patients with ulcerative colitis (UC), three patients with Crohn's disease (CD), and seven control subjects. Metabolically functional radioiodinated C3 was isolated from fresh human plasma. The fractional catabolic rates for ^{125}I-labeled C3, expressed as percent of the intravascular pool per hour, were increased ($p<0.0025$) in patients with inflammatory bowel disease (UC, mean 3.01 ± 0.17; CD, mean 3.23 ± 0.14) as compared to the controls (mean 2.05 ± 0.19). The synthesis rate of C3 also increased in UC and CD patients ($p<0.001$). The mean synthesis rate of C3 among CD patients was higher (3.55 ± 0.805 mg/kg/hr) than among UC patients (1.853 ± 0.582 mg/kg/hr, $p<0.05$), and both of these rates were higher than the control rate (1.194 ± 0.110 mg/kg/hr). However, the serum C3 levels were normal (UC, mean 128 ± 20 mg/100 ml) or raised (CD, 184 ± 16 mg/100 ml) in patients with inflammatory bowel disease, the control value being 132 ± 10 mg/100 ml. Thus, there was a significant positive correlation between the fractional catabolic rate of C3 and albumin ($p<0.05$), but no correlation of this rate with serum concentration, among the patients. The results suggest that complement activation may play a role in the pathogenesis of mucosal inflammation in UC and CD.

1348 ELECTROCARDIOGRAPHIC ALTERATIONS IN ACUTE PANCREATITIS. (Spa.) Bartolome-E., J.; Garnacho, A.; Frison, J. C.; Valle, V.; Rubies-Prat, J. (Ciudad Sanitaria de la Seguridad Social, Universidad Autonoma, Barcelona, Spain). *Rev. Esp. Enferm. Apar. Dig.* 49(4):539-544; 1977.

The electrocardiogram (ECG) patterns of 40 patients treated for acute pancreatitis were studied to evaluate the incidence and establish the type of ECG alterations in these patients. In 18 patients, the ECG's were normal. Abnormal ECG alterations in eight patients could not be properly evaluated. In four patients, ECG irregularities persisted after the acute phase of the disease: in a 70-yr-old man, ECG signs of myocardial necrosis persisted for 2 months with no evidence of elevated enzyme levels; 58-yr-old and 50-yr-old patients with pancreatic disease presented with ECG's characteristic of subepicardial ischemia that persisted for 2 months; and a 9-yr-old patient had an ECG indicative of a first degree auriculoventricular block, which continued for 1 yr after his pancreatitis was cured. Repolarization disorders were found in 10 patients; these disorders returned to normal 2-3 months after after the cure. The recognition of this ECG pattern in acute pancreatitis is an important aid in differentiating between acute pancreatitis and ischemic cardiopathy.

1349 ACUTE PANCREATITIS OF RARE CAUSATION. (Eng.) Pellegrini, C. A.; Acosat, J. M.; Skinner, D. B. (Univ. Chicago Hosp., Chicago, IL). *Surg. Gynecol. Obstet.* 144(6):899-902; 1977.

The cases of eight patients with acute pancreatitis resulting from rare causes are presented. Obstruction of the common pancreatic duct occurred in four patients, and pancreatitis in the remaining four patients resulted from direct parenchymal injury or vascular lesions. In two cases, the ampulla of Vater was obstructed by a foreign body (a T tube in one and a hydatid membrane in the other). In a third patient, obstruction of the pancreatic duct by a tumor resulted in pancreatitis and pseudocyst formation distal to the mass. In a fourth patient, the patency of the pancreatic duct and the more severe and generalized pancreatic injury suggested that mechanisms other than obstruction were involved in the development of acute pancreatitis in association with pancreatic carcinoma. In another patient, pancreatitis was limited to the portion of the pancreas that was to the left of the point of obstruction (a benign stricture of the proximal portion of the main pancreatic duct); a pancreaticojejunostomy provided successful decompression of the obstructed pancreas in this case. In the sixth patient, hyperparathyroidism associated with a large adenoma appeared to be the primary cause of pancreatitis, and this was successfully treated by parathyroidectomy. In the remaining patients, pancreatitis was caused by celiac axis thromboembolism and periarteritis nodosa involving the arterioles of the pancreas, resp. Necrosis occurred in both cases. Surgery is the treatment of choice for pancreatic duct obstruction.

1350 ACUTE PANCREATITIS ASSOCIATED WITH GALLSTONES IN A TWELVE-YEAR-OLD GIRL. (Eng.) Pease, R. (St. James' Hosp., Leeds, England). *Aust. N.Z. J. Surg.* 47(1):87-89; 1977.

The case of a 12-yr-old girl with acute pancreatitis associated with gallstones is presented. The patient had a 1-yr history of intermittent attacks of epigastric pain associated with vomiting. Abdominal examination revealed striking rebound tenderness. Pancreatitis was diagnosed at the first operation, but multiple stones in the gallbladder were not detected, probably because they floated freely within the viscid bile. Three weeks postoperatively, the patient's symptoms returned, and an oral cholecystogram demonstrated multiple small stones. At cholecystectomy, the gallbladder was found to contain 32 small faceted stones. The patient has remained asymptomatic since the second operation. Although pancreatitis is a rare disease in childhood, this diagnosis should be considered in cases of unusual abdominal pain, especially when associated with clinical evidence of ascites.

1351 NUTRITIONAL ASPECTS OF CHRONIC PANCREATITIS IN VERONA, ITALY. (Eng.) Vantini, I.; Cavallini, G.; Angelini, G.; Piubello, W.; Bovo, P.; Benini, L.; *et al.* (III Clinica Medica dell'Universita di Padova, 37100 Verona, Italy). *Rend. Gastroenterol.* 9(1):13-17; 1977.

Nutritional habits before the clinical onset of well-defined chronic relapsing pancreatitis were evaluated in 67 patients from Verona, Italy and 67 paired controls from the same region. The caloric intake of the patients with pancreatitis was significantly higher than that in the controls, both when the total intake (including alcohol) and the alimentary calories were considered ($p<0.001$). The absolute mean intake of proteins, fats, and carbohydrates in the patients (155.9 ± 64.2, 110.5 ± 47.6, and 432.6 ± 192.7 g/day) was significantly higher than that of the controls (112.3 ± 34.6, 77.2 ± 20.8, and 291.6 ± 86.9 g/day, resp., $p<0.001$), but when the data were expressed as percentages of the alimentary calories or of total calories, these differences were not significant.

1352 A SWISS FAMILY WITH HEREDITARY CHRONIC RECURRENT CALCIFYING PANCREATITIS. (Ger.) Bieler, M.; Hammer, B. (Medizinische Klinik, Kantonsspital, CH-9006 St. Gallen, Switzerland). *Schweiz. Med. Wochenschr.* 107(29):1035-1040; 1977.

Hereditary chronic recurrent calcifying pancreatitis in a Swiss family is reported. The disease was confirmed in five patients, the mother and her four children. The age at manifestation of the disease (episodic abdominal pains with emesis) ranged from 8 to 20 yr. Four of the five patients have had diabetes mellitus since the age of 15-40 yr. The fecal fat content was increased in three cases (25.6-53.3 g/day); the fecal chymotrypsin level was 5-48 μg/g versus a normal value of >130 μg/g; and the fecal trypsin level was 2-11 μg/g versus a normal level of >30 μg/g. Lysine and cystine were found in the urine at low, nonpathologic levels. Four other members of the family (the mother's father, her brother, the brother's son, and one of the mother's grandchildren) are suspected of having this disease. Twenty-five families with this disease have been reported in the literature. It is inherited as an autosomal dominant disorder; its pathogenesis is unknown. It is possible that an abnormal pancreatic juice is produced, which causes intracanalicular calcification. The treatment is identical to that of nonhereditary forms, i.e., generally conservative.

1353 EFFECT OF CAERULEIN ON γ-GLUTAMYL TRANSPEPTIDASE AND ALKALINE PHOSPHATASE IN THE DUODENAL JUICE IN CHRONIC PANCREATITIS. (Eng.) Delcourt, A.; Mesa, A.; Wettendorff, P.; Van Melsen, A. (Hopital d'Ixelles, Bruxelles, Belgium). *Digestion* 15(5):385-389; 1977.

The mechanism involved in the abnormally high output of γ-glutamyl transpeptidase (GGT) and alkaline phosphatase (AP) in the duodenal juice in chronic pancreatitis (CP) was investigated in 10 fasted normal controls, 10 patients with chronic pancreatitis, and 3 cholecystectomized patients. The increase of AP and GGT was significantly higher ($p<0.001$) in CP patients than in controls after the administration of cerulein (i.v. for 80 min at 75 ng/kg/hr). This abnormality was not limited to the calcifying type, since among the 10 cases studied only 6 presented pancreatic calcifications. The parallelism of the increase in output of GGT and AP in control and CP patients suggests that same mechanism is involved in both cases. However, the presence of a functioning gallbladder is necessary for this effect to occur, since in cholecystectomized patients and in the patient with T-tube drainage of the biliary tract no increase of GGT was observed after the administration of increasing doses of cerulein in single shots. The effect is not related to the discharge of large amounts of the enzymes by the diseased pancreas. It is suggested that the difference between controls and CP patients is related to an abnormality of the biliary system associated with chronic pancreatitis.

LIVER AND BILIARY TRACT

1364 ASSESSMENT OF THE PLASMA DISAPPEARANCE OF CHOLYL-1^{14}C-GLYCINE AS A TEST OF HEPATOCELLULAR DISEASE.

(Eng.) Thjodleifsson, B.; Barnes, S.; Chitranukroh, A.; Billing, B. H.; Sherlock, S. (Landspitalinn, Reykjavik, Iceland). [illegible](9) 697-70[illegible]; 1977.

To assess the value of the plasma disappearance of cholyl-1^{14}C-glycine for the detection of hepatic dysfunction, the plasma disappearance of a tracer dose of cholyl-1^{14}C-glycine (10 μCi, 0.2 μmol, i.v.) was examined in 12 control subjects and in 32 patients with hepatocellular dysfunction. Simple analysis of the data did not detect hepatic dysfunction except in the nine patients with severe hepatocellular disease. The greatest degree of discrimination between normal subjects and patients with mild liver disease was obtained by taking the ratio of the plasma retention at 60 min to that at 10 min; it was similar to that obtained with serum γ-glutamyltransferase. The 2-hr postprandial plasma total bile acid concentration gave complete separation between the control subjects and patients with liver disease. This study shows that the plasma disappearance of a tracer dose of cholyl-1^{14}C-glycine is not a sensitive test of hepatic dysfunction.

1365 DIAGNOSTIC USEFULNESS OF PLASMA CARCINOEMBRYONIC ANTIGEN LEVELS IN ACUTE AND CHRONIC LIVER DISEASE.

(Eng.) Bullen, A. W.; Losowsky, M. S.; Carter, S.; Patel, S.; Neville, A. M. (St. James' Hosp., Leeds LS9 7TF, England). *Gastroenterology* 73(4):673-678; 1977.

Plasma carcinoembryonic antigen (CEA) levels were measured in 87 patients with liver disease and in 25 controls to assess its value in the diagnosis of acute and chronic liver diseases. Raised plasma CEA levels were found in over 90% of 71 patients with chronic liver disease and 50% of 16 patients with acute liver damage (mean control value=12.1 ± 7.8 ng/ml). Levels increased with increasing chronicity and clinical severity of disease. In individual patients, the plasma CEA level fluctuated with the clinical condition. Persistently normal levels were never found in patients with chronic liver disease in poor clinical condition. A very high level suggests a bad prognosis. If CEA is considered together with the SGPT level, a discriminant function can be calculated, separating patients with acute liver damage and those with an acute exacerbation of chronic active hepatitis, with a high degree of certainty. In acute damage, peak CEA levels occur later than the time of maximum liver necrosis, suggesting that the rise is not owing to release of CEA from damaged cells. There is no significant difference in CEA level between patients with and without spontaneous or surgical portosystemic shunts, suggesting that high levels are not attributable to bypass of the liver. The timing of the rise in CEA in acute liver damage suggests that raised levels may be associated with regeneration. The tendency for higher levels to occur in those patients with greater disturbance of liver function suggests altered metabolism or excretion of CEA.

1366 MODIFICATION OF γ-GLUTAMYL TRANSPEPTIDASE IN LIVER DISEASE.

(Ita.) Ragaini, S.; Peracino, A.; Marcovina, S.; Ronchi, E.; Ballini, A.; Mojoli, M. (Ospedale Generale Provinciale di Treviglio e Caravaggio, Italy). *Minerva Med.* 67(43): 2805-2818; 1976.

γ-Glutamyl transpeptidase (GGT) levels were determined in 226 patients, including 20 healthy controls, 118 alcoholics (acute, 18 and chronic, 100), 53 patients with liver cirrhosis, 15 with cholelithiasis without obstructive jaundice, 5 with cholangitis, 6 with chronic aggressive hepatitis (CAH), and 9 with hepatocarcinomas. Increased GGT levels were unusually the result of nonspecific enzyme induction by drugs or alcohol, nonspecific liver damage, or the presence of intra- or extrahepatic cholelithiasis. The majority of patients had one or more of these factors present concurrently. Although elevated GGT levels were present in several conditions, they were determined to be a result of nonspecific induction rather than an indication of the disease state. GGT levels returned to normal when the inducing agent or causative factor was removed from the patient. In CAH and hepatocarcinoma, however, GGT levels were specifically related to the disease state and for a time were the only clinical indications of disease. After correcting for the use of drugs or

lcohol, GGT levels are a precise indication of
hese two diseases.

367 CORRELATIONS BETWEEN ANATOMICAL AND CLIN-
ICAL FEATURES IN LIVER DISEASE PATIENTS
ITH CIRCULATING ANTIBODY OF UNKNOWN ORIGIN. (Ita.)
erme, G.; Rizzetto, M.; Crivelli, O.; Bonino, F.
Ospedale Mauriziano, Turin, Italy). *Minerva Gas-
roenterol.* 22(3):219-226; 1976.

ntinuclear (AN), anti-smooth muscle (ASM), anti-
itochondrial (AMT), antimicrosomal (AMC), and
ntireticular (AR) antibodies were determined by
mmunofluorescence in 1,000 consecutive patients
xamined in the gastroenterology division of Mauri-
ian Hospital. Of the 1,000 patients, 267 had liver
isease with primary parenchymal involvement; 254
ad liver disease with secondary parenchymal in-
olvement, cholelithiasis, or metastases; and 458 had
astrointestinal disease with no evidence of liver
nvolvement. Thirty-three percent of patients with
rimary parenchymal involvement, 6.3% with secondary
arenchymal involvement, and 5.9% with no liver in-
olvement were positive for one or more of the anti-
odies studied. Of the primary parenchymal involve-
ent patients, 65% had acute hepatitis, 59% had
hronic active hepatitis (CAH), 38% had hepatomas,
3% had sclerosing liver disease, and 20% had in-
ctive cirrhosis. ASM antibodies were found in the
ajority of cases; CAH and inactive cirrhosis pa-
ients were AR positive; only CAH patients were AMC
ositive. ASM antibodies were associated with AN
tibodies except in acute hepatitis, where only
% of the patients were AN positive. In order of
requency, patients were positive for ASM, AN, AMT,
IC, and AR. A subgroup of CAH patients according
a single serological marker could not be iden-
ified. There are chronic liver diseases that are
stinct from those of viral etiology or metabolic
sfunction and that are most likely autoimmune
origin.

68 RELATIVE VALUE OF SELECTIVE ARTERIOGRAPHY
AND LAPAROSCOPY IN THE DIAGNOSIS OF HE-
TIC CARCINOMA. (Spa.) Perez-Jimenez, F.; San
rtin, P.; Muro, J.; de Dios, J.; Segura, J. M.
Cuidad Sanitaria de la Seguridad Social "La Paz,"
drid, Spain). *Rev. Esp. Enferm. Apar. Dig.* 47
):93-100; 1976.

comparison is made of selective arteriography and
paroscopy in the diagnosis of hepatocarcinoma.
paroscopy allows the direct visualization of the
dominal viscera and the detection not only of the
istence of a tumor, but also of its size, local-
zation, and nature. On the other hand, since he-
tocarcinoma is generally a hypervascularized tumor
eferentially nourished by the hepatic artery,
teriography is also an important diagnostic tool.
paroscopy is contraindicated in cases of cardio-
lmonary insufficiency and alterations in the
neral circulation. On the other hand, arterio-
aphy is dangerous when there are alterations in
ood coagulation. Moreover, there may be ana-
ylactic problems, and there is also the inherent
risk in the manipulation of arteries with atheromatosis. However, arteriography is generally better tolerated by patients. Arteriography is superior to laparoscopy for the determination of the state of the organ and is a tremendous aid to the surgeon in his planning and handling of a resection; laparoscopy permits only the recognition of the state of the peritoneum and the abdominal viscera accessible to such exploration. The authors conclude that arteriography should be the first diagnostic procedure employed when hepatocarcinoma is suspected. Only when the results of the arteriography are doubtful or when the state of the peritoneum and the resting liver needs to be evaluated for therapeutic purposes should laparoscopy be the final exploratory tool in the systematic diagnosis of hepatic tumors.

1369 CONTRIBUTIONS OF LAPAROSCOPE-DIRECTED BIOPSIES TO THE DIAGNOSIS OF PRIMARY NEOPLASMS OF THE LIVER. (Ita.) Fedeli, G.; Anti, M.; Montano, A. M.; Rapaccini, G. L.; Pizzolato, G. P. (Universita Cattolica del S. Cuore, Istituto di Patologia Speciale Medica e Metodologia Clinica, Rome, Italy). *Minerva Med.* 68(25):1709-1718; 1977.

The use of laparoscopy as a diagnostic tool is discussed. Laparoscope-directed biopsies of the liver are very important in the diagnosis of liver disease, particularly the early diagnosis of neoplasms and in the differentiation of benign and malignant liver tumors. Laparoscopic biopsy reduces diagnosis time and presents little or no risk to the patient. A review of the literature and the authors' personal observations with this technique are presented.

1370 PRIMARY LIVER CELL CARCINOMA (PLCC) IN THE NORTHERN GUINEA SAVANNA OF NIGERIA. (Eng.) Fakunle, Y. M.; Ajdukiewicz, A. B.; Greenwood, B. M.; Edington, G. M. (Dept. Medicine, Ahmadu Bello Univ., Zaria and Kaduna, Nigeria). *Trans. R. Soc. Trop. Med. Hyg.* 71(4):335-337; 1977.

The frequency of primary liver cell carcinoma (PLCC) and the clinical and pathological findings in patients with PLCC were studied in the Guinea Savanna country of Nigeria, an area that has one of the highest frequencies of PLCC in the world. During 1973 and 1974, 185 of 1,170 malignancies were diagnosed as PLCC. The highest frequency occurred among men aged 20-49 yr. Abdominal swelling, pain, hepatomegaly, and ascites were the most common symptoms. Hypoalbuminemia (<3 g%) was present in 67% of the examined cases. Alpha$_1$-fetoprotein occurred in 85% of the 172 patients tested. Hepatitis B surface antigen was detected in 49% of 138 patients. Histologically the tumors were well described and trabecular, with a few showing adenoid or clear cell areas. Liver cell dysplasia was present in almost all cases. These clinical and laboratory findings are similar to those in other series in Africa.

1371 HEMOSTATIC FACTORS IN PRIMARY HEPATOCELLULAR CANCER.

(Eng.) van der Walt, J. A.; Gomperts, E. D.; Kew, M. C. (South African Inst. Medical Res., Johannesburg, 2000, South Africa). *Cancer* 40(4):1593-1603; 1977.

Detailed coagulation studies were performed in 19 South African black men with primary hepatocellular cancer (PHC), and the results were compared with those in 19 age-matched controls. Various functional and immunochemical methods were employed in determining the possible presence of functional or structural coagulant protein abnormalities. The patient group was characterized by prolonged prothrombin times ($p<0.001$), partial thromboplastin times ($p<0.001$), and Reptilase times ($p<0.001$); increased levels of fibrinogen, factor VIII, and factor VIII-related antigen; moderately decreased levels of factor V, factor IX, factor X, antithrombin III, and plasminogen; and reduced levels of factor II and factor VII (all $p<0.001$). Functional, immunochemical, and biochemical analysis failed to detect the presence of acquired protein abnormalities. These findings indicate that hemostatic changes in primary hepatocellular cancer are nonspecific in character. Severe alterations in the plasma levels of one or more of these hemostatic factors may occur.

1372 SERUM GLUTAMIC OXALACETIC TRANSAMINASE/GLUTAMIC PYRUVIC TRANSAMINASE RATIOS IN HEPATOCELLULAR CARCINOMA.

(Eng.) Shimokawa, Y.; Okuda, K.; Kubo, Y.; Kaneko, A.; Arishima, T.; Nagata, E.; *et al.* (Kurume Univ. Sch. Medicine, Kurume, Japan). *Cancer* 40(1):319-324; 1977.

Changes in SGOT levels and in the SGOT/SGPT ratio were examined in 131 patients with hepatocellular carcinoma (HCC), 76 patients with metastatic liver carcinoma (MLC), and 234 patients with liver cirrhosis. At the onset of the diseases, the SGOT levels in the 39 patients with HCC without cirrhosis, the 92 patients with HCC with cirrhosis, the 234 with cirrhosis alone, and the 76 with metastatic carcinoma were 96 ± 12, 152 ± 14, 84 ± 17, and 64 ± 17 U, resp. The SGPT levels were 42 ± 5, 54 ± 5, 55 ± 4, and 38 ± 5 U, resp., and the SGOT/SGPT ratios were 2.5 ± 0.2, 3.5 ± 0.3, 1.9 ± 0.1, and 2.2 ± 0.1, resp. The differences in SGOT and SGOT/SGPT ratio between the patients with cirrhosis and those with HCC and cirrhosis were highly significant ($p<0.01$). In all patients with HCC, there was a continuous increase in the SGOT level 2-3 months before death, while SGPT remained almost unchanged. In the patients with MLC, a similar, but less prominent change occurred in the preterminal period. Although the LDH activities increased in all groups during the 2 months before death, this was most striking in MLC. The average SGPT level was lower in HCC patients without cirrhosis at autopsy, compared with those with HCC and cirrhosis ($p<0.01$), making the SGOT/SGPT ratio greater in the former patients. The SGPT level was lower in patients with a liver weighing more than 3,500 g than that in patients with a liver weighing less than 1,500 g; since the SGOT level was not much different, the SGOT/SGPT ratio was greater in the former ($0.05> p>0.1$).

1373 MULTIPLE TUMORS AFTER ANDROGEN THERAPY.

(Eng.) Sale, G. E.; Lerner, K. G. (Fred Hutchinson Cancer Res. Center, 1124 Columbia St., Seattle, WA 98104). *Arch. Pathol. Lab. Med.* 101 (11):600-603; 1977.

A case of multiple hepatomas with early peliosis hepatis, multiple pancreatic islet cell tumors, and a renal medullary interstitial cell tumor following 5 yr of androgen and prednisone therapy for idiopathic aplastic anemia is reported. The patient, a 37-yr-old man, died shortly after allogeneic bone marrow transplantation. The hepatic tumors were small and well differentiated, and the pancreatic tumors were of mixed ribbon and islet cell pattern. During the 5-yr period, the patient had received testosterone, oxymetholone, methyltestosterone, fluxymesterone, and prednisone. The tumors in this case probably represent part of a continuum similar to those induced in experimental rats by a combination of carcinogen and androgens, and it would thus seem prudent to designate the hepatomas as adenomas or as hepatomas with variable malignant potential. Exploration of a possible trophic role of androgens or corticosteroids for the renomedullary interstitial cell may be warranted for the study of the renal tumor in this patient.

1374 HEPATOPORTAL ARTERIOVENOUS FISTULA IN PRIMARY CARCINOMA OF THE LIVER.

(Eng.) Nagasue, N.; Inokuchi, K.; Kobayashi, M.; Saku, M. (Kyushu Univ. Sch. Medicine, Fukuoka, Japan). *Surg. Gynecol. Obstet.* 145(4):504-508; 1977.

The correlation between portal circulation and esophageal varices was evaluated in 80 patients with a primary hepatic carcinoma, with special regard to the significance of the presence of hepatoportal arteriovenous fistula. Hepatoportal arteriovenous fistula was found in eight patients. Esophageal varices were observed in 32 of the patients with a hepatoma. Seventeen of 52 patients without hepatoportal arteriovenous fistula had varices compared with all patients with a fistula. A fatal hemorrhage was encountered in five patients with the fistula. A rational treatment for those with the triple lesions (hepatoma, esophageal varices, and hepatoportal arteriovenous fistula) may be a ligation of the hepatic artery.

1375 BENIGN HEPATOCELLULAR TUMORS.

(Eng.) Guzman, I. J.; Gold, J. H.; Rosai, J.; Schneider, P. D.; Varco, R. L.; Buchwald, H. (Univ. Minnesota Medical Sch., Minneapolis, MN 55455). *Surgery* 82(4):495-503; 1977.

All cases diagnosed as benign hepatocellular tumors occurring at the University of Minnesota Hospitals from 1950 to 1976 are summarized, and the tumor pathology, clinical aspects, and possible associatio with the use of oral contraceptives are discussed. Excluding hemangiomas, 40 tumors were reviewed and reclassified. Eighteen were diagnosed as focal nodular hyperplasia (FNH), 10 as hepatocellular adenomas (HCA), 11 as bile duct adenomas (BDA), and 1 as a mesenchymal hematoma. Among the patients with FNH, the female:male ratio was 8:1, and the mean age was 43 ± 18 yr. Two patients were symptomatic; of these, one presented with portal hypertension. Treatment consisted of local resection in 12, left hepatectomy in 1, and right hepatectomy in 2. Eight patients had a history of oral contraceptive or other steroid intake. The tumors occurring after 1964 were larger ($p<0.05$). In the patients with HCA, the female:male ratio was 4:1, and the mean age was 33 ± 20 yr. Five tumors were found at necropsy; the other five were symptomatic. Treatment consisted of local resection in one patient, right hepatectomy in two, and left hepatectomy in one. Three patients had a positive history of oral contraceptive intake. There was no statistically significant difference in the size or the incidence of hepatocellular adenomas between 1950 to 1963 and 1964 to 1976. In BDA, the female: male ratio was 7:4, and the mean age was 57 ± 15 yr. Only one case was symptomatic, and the lesion in this patient measured 10 cm. The other BDA's were 1 cm or less in diameter. There is no suggestion that these tumors are associated with use of birth control pills. This series has a lower proportion of symptomatic patients and of patients on oral contraceptives than is suggested by reviewing the literature. It is concluded that a causal relationship between use of oral contraceptives, or other steroids, and benign hepatocellular tumors cannot be demonstrated. However, this conclusion does not rule out that oral contraceptives, or other steroids, might have a contributory influence on the initiation of certain of these tumors or on tumor size.

1376 SERUM-FERRITIN IN DIAGNOSIS OF HAEMOCHROMATOSIS: A STUDY OF 43 FAMILIES.

(Eng.) Halliday, J. W.; Cowlishaw, J. L.; Russo, A. M.; Powell, L. W. (Royal Brisbane Hosp., Brisbane, 4029, Queensland, Australia). *Lancet* 2(8039): 621-623; 1977.

Two hundred forty-two members of 43 families with idiopathic hemochromatosis were investigated for increased body-iron stores to assess the value of serum ferritin determination as a screening test to detect preclinical disease. The serum iron concentration was elevated in only 76% of relatives with increased iron stores, and it was also elevated in 10% of relatives with normal iron stores. The percentage saturation of transferrin was elevated in all relatives with increased iron stores but also in 33% of relatives with normal iron stores. Serum ferritin was raised in 98% of relatives with increased iron stores and in only three (1.8%) of those with normal iron stores. These three subjects consumed alcohol in excess of 100 g ethanol daily, and their serum ferritin levels fluctuated widely. Increased iron stores were reflected in increased serum ferritin concentrations in subjects as young as 14 yr in whom the liver iron concentration was twice the normal upper limit and before there was any evidence of architectural damage to the liver. The serum ferritin concentration is a useful noninvasive screening test for precirrhotic hemochromatosis.

1377 INFLUENCE OF DEOXYCHOLIC ACID ON BILIARY LIPIDS IN MAN.

(Eng.) Ahlberg, J.; Angelin, B.; Einarsson, K.; Hellstrom, K.; Leijd, B. (Karolinska Institutet at Serafimerlasarettet, Stockholm, Sweden). *Clin. Sci. Mol. Med.* 53(3): 249-256; 1977.

To gain information about the possible influence of deoxycholic acid on the composition of bile, the duodenal bile acid composition was analyzed in 24 control subjects and 107 patients with various types of hyperlipoproteinemia. A highly significant negative correlation was observed between the proportions of deoxycholic acid and cholic acid ($r=-0.80$, $p<0.001$) as well as between deoxycholic acid and chenodeoxycholic acid ($r=-0.58$, $p<0.001$). The patients with gallbladder disease had an increased proportion of deoxycholic acid in their bile. Eight controls were studied before and during the ingestion of 1.9 mmol (0.75 g) of deoxycholic acid daily. In these subjects, a rise in the proportion of deoxycholic acid was also accompanied by a fall in the proportion of both cholic acid and chenodeoxycholic acid in duodenal bile. The biliary lipid composition and cholesterol saturation was determined before and during the administration of 1.9 mmol (0.75 g) of chenodeoxycholic acid (12 patients) or deoxycholic acid (8 patients) daily for 3-4 weeks. The cholesterol saturation was decreased during the chenodeoxycholic acid ingestion (from 10.2 ± 0.7% of total bile lipids to 7.2 ± 0.7%, $p<0.001$), whereas no change occurred in bile saturation during deoxycholic acid administration. The ingestion of chenodeoxycholic acid lowered serum triglyceride, and deoxycholic acid lowered the serum cholesterol. The mechanisms and significances of these findings remain to be determined.

1378 THE IMMUNOELECTRON-MICROSCOPICAL DEMONSTRATION OF ANTIBODIES AGAINST ENDOPLASMIC RETICULUM (MICROSOMES) IN CHRONIC AGGRESSIVE HEPATITIS AND LIVER CIRRHOSIS.

(Eng.) Storch, W.; Cossel, L.; Dargel, R. (Neurologischen Klinik der Karl-Marx-Universitat, DDR-7039, Leipzig, Karl-Marx-Stadter Str. 50, A 2, E. Germany). *Immunology* 32(6):941-945; 1977.

Indirect immunoelectron microscopic observations made on microsomal fractions of rat liver treated with microsomal antibodies obtained from the blood of patients with liver cirrhosis and hepatitis and incubated with peroxidase-labeled antihuman IgG are reported. Microsomal antibodies were detected in the sera of 18 subjects among 1,911 patients included in the investigation. Seven of these 18 patients had chronic aggressive hepatitis, 1 had persistent hepatitis, and 10 had liver cirrhosis. In microsomal fractions treated with serum antibodies from these patients, the fragments of endoplasmic reticulum (microsomes) were less densely packed and less contrasting than in control microsomal fractions that were not treated with sera from patients with microsomal antibodies. Extremely fine granular to amorphous (homogenous) material of high electron density was observed to be localized at the sites of microsomal membranes (fragments of endoplasmic reticulum) so that ring-shaped structures (or vesicles) having relatively thick-walled borders of different width and high electron density were produced. These results were not obtained in parallel tests with control microsomal fractions that were not treated with the microsomal antibodies. The fine granular to amorphous deposits of high electron density may be the substrate of an antibody reaction against membranes of the endoplasmic reticulum, made visible by the aid of peroxidase-labeled antibodies. The results suggest that the antibody reaction is chiefly directed towards the membranes of the endoplasmic reticulum.

1379 NONFUNCTIONING ARGYROPHILIC TUMOR (APUDoma) OF THE HEPATIC DUCT. SIMPLIFIED METHODS OF DETECTING BIOGENIC AMINES IN TISSUE. (Eng.) Judge, D. M.; Dickman, P. S.; Trapukdi, S. (Milton S. Hershey Medical Center, Hershey, PA 17033). *Am. J. Clin. Pathol.* 66(1):40-45; 1976.

LIVER AND BILIARY TRACT

Hyperbilirubinemic States

1404 LIVER DISEASE IN INFANTS. PART II: HEPATIC DISEASE STATES. (Eng.) Mathis, R. K.; Andres, J. M.; Walker, W. A. (Massachusetts Hosp., Boston, MA 02114). *J. Pediatr.* 90(6):864-880; 1977.

A review is presented of the developmental and acquired disorders of bilirubin metabolism (other than hepatic excretory defects) in infants. Noncholestatic jaundice (unconjugated hyperbilirubinemia) of various types (e.g., physiologic jaundice), jaundice due to overproduction of bilirubin, and jaundice due to impaired transport, hepatic uptake or conjugation, or enterohepatic circulation of bilirubin are discussed together with the treatment of these entities. Different types of cholestatic jaundice (conjugated hyperbilirubinemia) are described: idiopathic cholestatic jaundice, inherited cholestatic jaundice (familial hepatocellular cholestasis and metabolic hepatocellular cholestasis), inherited "noncholestatic" jaundice, and acquired cholestatic jaundice. Infectious liver disease of infants (e.g., viral hepatitis, sepsis, and abscess) and iatrogenic liver disease due to chemical liver injury, i.v. alimentation, or injury due to catheter placement in umbilical vessels, or ionizing irradiation are also described. It is suggested that every step in the metabolism of bilirubin can be affected by a spectrum of conditions causing jaundice and that hyperbilirubinemia in neonates and infants should be regarded as abnormal until proven otherwise.

1405 UNCONJUGATED BILIRUBIN AND AN INCREASED PROPORTION OF BILIRUBIN MONOCONJUGATES IN THE BILE OF PATIENTS WITH GILBERT'S SYNDROME AND CRIGLER-NAJJAR DISEASE. (Eng.) Fevery, J.; Blanckaert, N.; Heirwegh, K. P. M.; Preaux, A. M.; Berthelot, P. (Dept. Medical Res., Univ. Leuven, 300 Leuven, Belgium). *J. Clin. Invest.* 60(5):970-979; 1977.

Bilirubin pigments were studied in the bile of 20 normal adults, 25 patients with Gilbert's syndrome, 9 children with Crigler-Najjar disease, and 6 patients with hemolytic diseases (congenital spherocytosis or autoimmune hemolysis), to determine how hepatic bilirubin uridine diphosphate (UDP)-glucuronosyltransferase deficiency affects the end products of bilirubin biotransformation. In bile from patients with Gilbert's syndrome, there was a striking increase in the proportion of bilirubin monoconjugates (48.6 ± 9.8% of total conjugates) relative to that in normal bile (27.2 ± 7.8%). This increase was even more pronounced in children with Crigler-Najjar disease, in whom bile glucuronide was always demonstrated. Furthermore, unconjugated bilirubin-IXα was always present in the bile of these children and amounted to 30-57% of their total bilirubin pigments (<1% in the controls). It was not possible to predict from the biliary bilirubin composition whether a child would respond to phenobarbital therapy. Bile composition was normal in patients with hemolysis, except when there was associated deficiency of hepatic glucuronosyltransferase. Therefore, the observed alterations were not a simple consequence of unconjugated hyperbilirubinemia. The findings suggest that Crigler-Najjar disease represents a more pronounced expression than Gilbert's syndrome of a common biochemical defect. Hepatic bilirubin UDP-glucuronosyltransferase deficiency leads to decreased formation of diconjugates with an ensuing increase in the proportion of bilirubin monoconjugates in bile; in the most severe cases, an elevated content of biliary unconjugated bilirubin is also found.

1406 PHYSIOPATHOLOGICAL AND THERAPEUTIC FEATURES OF GILBERT'S ICTERUS AT THE PRESENT TIME. I. RECENT FINDINGS IN GILBERT'S SYNDROMES. (Ita.) Lovisetto, P.; Giorcelli, W.; Actis, G. C.; Biarese, V. (Istituto di Clinica Medica Generale e Terapia Medica I, Universita degli Studi di Torino, Turin, Italy). *Minerva Med.* 67(35):2253-2265; 1976.

Gilbert's icterus is a term used to describe some forms of free-bilirubin hyperbilirubinemia that are caused by a defect in bilirubin clearance by liver cells. Gilbert's icterus occurs in 4-6% of the population and appears to be an inherited metabolic disturbance in which there is a reduction in glucuronyl transferase activity. In certain individuals, there is an alteration in the capacity of the liver cells to retain bilirubin that has been removed from the blood. Gilbert's icterus is of two types: one with slight bilirubinemia that is a result of defective uptake and one with higher bilirubin that is due to a reduction in glycuronide conjugation. Lysosome-like granules are seen at the biliary pole of the liver in Gilbert's syndrome patients. The role of these granules in the disease process is not known. Clinical examination sometimes reveals slight hepatomegaly and a more or less intense icterus. On laboratory examination, the average life of erythrocytes may be shortened and kinetic studies with free bilirubin or with radiolabeled bilirubin may show alterations in a selected parameter. Most Gilbert's icterus patients are asymptomatic, however.

1407 PHENOBARBITAL PROPHYLAXIS OF NEONATAL HYPERBILIRUBINEMIA: EVALUATION OF A NIGHTLY DOSE. (Eng.) Thomas, C. R. (Southside OB/GYN, Inc., 3530 South Keystone Ave., Suite 111, Indianapolis, IN 46227). *Obstet. Gynecol.* 50(5): 607-610; 1977.

An attempt was made to improve the success of a previously described method of preventing neonatal hyperbilirubinemia. Two hundred twelve women received phenobarbital in a single 30-mg nightly dose from 32 weeks of gestation until delivery, and the incidence of jaundice in their infants was compared with that in the infants of 254 untreated mothers. A 39% reduction in significant hyperbilirubinemia was realized, but this fell far short of previous findings with a larger dose. Premature infants received no apparent protection against jaundice. No mature infants had severe jaundice (>16 mg/100 ml), and the resolution of hyperbilirubinemia in this group was more rapid. No apparent difference in drowsiness or daytime sedation from previous experience was found. Female newborns responded much better (3:1) to prophylaxis. These disappointing results favor a return to the 1-g daily divided dose.

1408 IMPAIRED DRUG CONJUGATION IN SUBJECTS WIT GILBERT'S SYNDROME (GS) [Abstract]. (Eng Kutz, K.; Schulte, A.; Jensen, C.; Gugler, R. (Medizinische Poliklinik, Univ. Bonn, Bonn, W. Germany). *Gastroenterology* 73(5):1229; 1977.

Nonviral Hepatitis and Hepatic Injury

1410 HEPATOTOXICITY OF ANESTHETICS. (Spa.) Hernandez, A. M. (Hospital Provincial, Murcia, Spain). *Rev. Esp. Enferm. Apar. Dig.* 47 (6):785-794; 1976.

The metabolism of anesthetics by the liver and the resultant hepatotoxicity of these agents are reviewed. The anatomy and normal physiological functions of the liver are described with special emphasis on drug metabolism. It is concluded that the majority of anesthetics may be considered "protoplasmic poisons." The types of hepatic lesions commonly associated with hepatic diseases and the diagnostic tests for hepatic function are enumerated. The choice of the type of anesthetic to use, particularly for a patient with a disease of the liver, requires careful consideration of the drugs that the liver will metabolize to excrete the anesthetic, and the use of anesthetics that are potentially hepatotoxic (chloroform, halothane, ethoxyfluorane, phenothiazine, and so on) should be avoided.

411 PORPHYRIA CUTANEA PRAEMATURA DUE TO HORMONAL CONTRACEPTIVES. (Ger.) Doss, M. Fach Klinische Biochemie im Fachbereich Humanedizin der Universitat, Pilgrimstein 2, 3550 arburg/Lahn, W. Germany). *Dtsch. Med. Wochenschr.* 02(23):875-877; 1977.

orphyria cutanea tarda (PCT) was diagnosed in four atients following long-term use of hormonal reparations. PCT was due to the use of oral ontraceptives in three 23- to 25-yr-old patients; two ad used Eugynon for 3 and 8 yr, resp., the third, rlest for 3 yr. PCT was also found in a 65-yr-old an who was treated with estrogens for prostate arcinoma. The genealogical investigation of one f the women revealed PCT in her father (probably anifested as a result of chronic alcoholism) and hronic hepatic porphyria type B without dermatoogical signs in her sister. Uroporphyrins were ominant in all patients, accounting for 51-63% f the total porphyrin, while heptacarboxyporphyrin ccounted for 19-43%, hexacarboxyporphyrin for -7%, pentacarboxyporphyrin for <1-7%, coproporhyrin for <1-7%, and tricarboxyporphyrin for up o 1%. The very low incidence of manifest PCT ompared to the large numbers of women using oral ontraceptives and patients treated with estrogens uggests that a defect in uroporphyrinogen ecarboxylase activity is a necessary condition f PCT. The enzymatic disturbance develops radually from the clinically symptom-free initial tages of chronic hepatic porphyria to PCT. ifferentiation between late and early forms of CT is not justified in view of the uniform pathoiochemical findings.

12 QUINIDINE-INDUCED HEPATITIS AND THROMBOCYTOPENIA. (Eng.) Alam, M.; Duvernoy, W. F. C.; Pickard, S. D.; Aronsohn, P. L. (Henry Ford Hosp., 2799 W. Grand Blvd., Detroit, MI 48202). *Henry Ford Hosp. Med. J.* 25(2):53-60; 1977.

The cases of four patients with quinidine-induced hepatitis are presented. Hepatitis was accompanied by malaise, anorexia, fever in two patients, and marked elevation of liver enzymes in all. Two patients had associated quinidine-induced thrombocytopenia of 81,000 and 6,600 platelets/mm^3, resp. Liver biopsy in two patients revealed small foci of hepatocellular necrosis, Kupffer cell hyperplasia, and Kupffer cells containing lipochrome. In one patient, noncaseous granulomatous lesions were seen. Symptoms subsided and laboratory tests returned to normal rapidly on withdrawal of quinidine. In one patient, drug challenge reproduced symptoms and abnormal liver function test results. Quinidine-induced hepatitis is probably more frequent than recognized heretofore and may be associated with quinidine-induced thrombocytopenia.

LIVER AND BILIARY TRACT

Acute Viral Hepatitis

1416 HEPATITIS A AND HEPATITIS B: DIFFERENTIAL CLINICAL, EPIDEMIOLOGICAL AND IMMUNOLOGICAL FEATURES. (Ita.) Ortana, L.; Pizzigallo, E.; Federico, G.; Camilli, G.; Laghi, V. (Istituto di Clinica Malattie Infettive, Universita Cattolica del Sacro Cuore, Rome, Italy). *Minerva Med.* 68(1): 13-28; 1977.

A study is presented of 136 patients with viral hepatitis. Radioimmunoassay of hepatitis B surface antigen (HBsAg) revealed that 58 were HBsAg positive and 78 were HBsAg negative. Mussels were responsible for the transmission of viral hepatitis in 33.33% of the HBsAg-negative group. The oral-fecal route of transmission was implicated in 85.9% of HBsAg-negative cases and 48.2% of HBsAg-positive cases. The average course of disease in hepatitis B and A, resp., was 51.7 and 36 days. Comparative determinations of the levels of transaminases, bilirubin, immunoglobulins, and complement revealed variations in behavior between two types of hepatitis. On the other hand, cellular immunity, studied by the E-rosette technique, appeared depressed in the initial phase of illness in both types of hepatitis, with return to normal upon clinical cure. Clinical cures in less than 60 days were achieved in 71.7% of the HBsAg-negative cases compared to 63.4% of the HBsAg-positive cases; indirect hyperbilirubinemia persisted in 3.7% and 6.8% of the HBsAg-negative and -positive cases, resp. Clinical cures in more than 60 days were achieved in 10.2% and 18.9% of HBsAg-negative and -positive cases, resp., with persistent indirect hyperbilirubinemia in 5.1% and 1.6% of the cases, resp. Continued elevation of transaminase levels were found in 8.9% and 6.8%, resp., of the HBsAg-negative and -positive subjects, who were dismissed from observation without further follow-up. The percentage of complete cures are about equal in the two types of hepatitis, although recovery is significantly faster in hepatitis A (HBsAg-negative hepatitis).

1417 ACUTE HEPATITIS: A PROGNOSTIC STUDY WITH OBSERVATION TIME UP TO 37 YEARS: A FOLLOW-UP STUDY OF THE IVERSEN/ROHOLM LIVER BIOPSY MATERIAL. (Eng.) Dietrichson, O.; Zoffmann, H.; Christoffersen, P.; Hilden, M.; Juhl, E.; Thomsen, A. C. (Kommunehospitalet, Copenhagen, Denmark). *Acta Med. Scand.* 202(4):271-276; 1977.

A follow-up study of 147 patients who had had hepatitis was performed 15-37 yr after the diagnostic biopsy, based on repeated liver biopsies, biochemical liver tests, autopsy reports, and death certificates. Two patients died from acute liver failure, and the development of cirrhosis was documented or strongly suspected in 22 patients. A comparison between these 24 patients and 86 patients with uncomplicated disease revealed a significantly larger number of women (79% versus 38%), a higher age (median 57 versus 40 yr), and more cases with piecemeal necrosis (83% versus 52%), confluent necrosis (54% versus 26%), and marked portal inflammation (83% versus 43%) at the time of the initial liver biopsy in the group with the poor prognosis. The results indicate that the prognosis can be determined by clinical and histological examination in patients with acute hepatitis.

1418 ACUTE VIRAL HEPATITIS IN ITALY: RESULTS OF A COLLABORATIVE STUDY. (Eng.) Guisti G.; Ruggiero, G.; Galanti, B.; Piccinino, F.; Sagnelli, E.; Lucchelli, P. E. (Univ. Naples, 1st Medical Sch. Naples, Naples, Italy). *Acta Hepatogastroenterol.* 24(4):226-237; 1977.

The etiological and clinical aspects of viral hepatitis were evaluated by a retrospective survey of 2,788 hospitalized Italian patients. Ninety percent of the patients had not been treated with steroids. For each case, the clinical and biochemical data were recorded, coded, computerized, a statistically analyzed. Viral hepatitis was more frequent among young patients (mean age, 26.3 yr; age range 1-75 yr; age range of highest incidence, 6-10 yr) and among men (male/female ratio, 1.26). The major factors affecting the severity of illness were age, sex, hepatitis B surface antigen (HBsAg), and transmission by blood transfusion. Both HBsAg-positive patients and older patients had deeper jaundice ($p<0.001$), longer hospitalization ($p<0.001$), higher rates of mortality, and more frequent progression to chronicity. Men had more prolonged jaundice, antigenemia, and hospitalization and a higher frequency of biochemic relapses. Furthermore, men predominated among those patients who progressed to chronicity or died of acute liver failure. In all age groups irrespective of the presence of serum HBsAg, post-transfusion hepatitis was more severe (deeper jaundice, longer hospitalization, and more frequent biochemic relapses, $p<0.01$ for all) than nontransfusion hepatitis. The death rate for all patients was 0.5% but was greater in men (0.64%), in patients over 50 yr of age (1.74%), and in transfused patients (1.58%). The lowest death rate (0.13%) was observed in children age 6-15. Age, sex, presence or absence of HBsAg, and history of blood transfusion were examined for interrelationships, and significant correlations for pairs of these parameters are given. Type B hepatitis was confirmed to be an occupational hazard for surgeons and nurses, consistent with previous observations. The need for prospective studies of viral hepatitis to permit accurate evaluation of outcome is stresse

1419 HEPATITIS B IN WARD AND CLINICAL LABORATORY EMPLOYEES OF A GENERAL HOSPITAL. (Eng.) Levy, B. S.; Harris, J. C.; Smith, J. L.; Washburn, J. W.; Mature, J.; Davis, A.; *et al.* (128 Hollis St., Sherborn, MA 01770). *Am. J. Epidemiol.* 106(4):330-335; 1977.

A sharp increase in viral hepatitis cases, mostly type B, among the 2,000 employees of a general hospital during 3 yr was investigated. Of the 38 cases, 22 occurred in nonphysician, ward employees. Of 189 current ward employees, 8% had antibody to hepatitis B surface antigen (anti-HBs) and 1% had hepatitis B surface antigen (HBsAg). Hepatitis B virus (HBV) seropositivity was highest for employees who worked closely with hemodialysis and renal transplant patients and for those who claimed that their ward was understaffed. Nine of the 38 cases occurred in clinical laboratory workers. Of 70 current laboratory employees, 17% were positive for anti-HBs and none for HBsAg. HBV seropositivity was highest for those working in the chemistry section (highest there among those performing blood-gas determinations and those working with the multichannel autoanalyzers) and those who routinely got blood on their skin and clothes at work. All seropositive employees worked routinely with blood. These data support the hypotheses that many hospital employees contract hepatitis B from exposure to HBsAg-positive patients and that many clinical laboratory employees contract it from exposure to HBV-contaminated blood.

1420 HEPATITIS-B VIRUS INFECTION IN ANAESTHETISTS.

(Eng.) Carstens, J.; Macnab, G. M.; Kew, M. C. (Baragwanath Hosp., Johannesburg, South Africa). *Br. J. Anaesthesiol.* 49(9):887-889; 1977.

To determine whether anesthetists are at risk of developing hepatitis B virus (HBV) infection from their patients, 95 anesthetists working with black South Africans (who have a high prevalence of hepatitis B antigenemia) were questioned about attacks of viral hepatitis, and their blood was tested for hepatitis B surface antigen (HBsAg) and antibody (anti-HBs) by radioimmunoassay. Anti-HBs was detected in the sera of 17.9% anesthetists, but none was a chronic carrier of HBsAg. Two anesthetists had acute viral hepatitis during their careers, one of whom is now positive for anti-HBs. Forty-five of the anesthetists (47.4%) were known to have anesthetized patients with HBs antigenemia, and of these seven were anti-HBs-positive. Anesthetists working with a population having a high carrier rate of HBV appear to be more at risk from HBV infection than the general population.

1421 SERUM ALPHA-FETOPROTEIN LEVELS IN PATIENTS WITH ACUTE AND CHRONIC LIVER DISEASE: RELATION TO HEPATOCELLULAR REGENERATION AND DEVELOPMENT OF PRIMARY LIVER CELL CARCINOMA.

(Eng.) Eleftheriou, N.; Heathcote, J.; Thomas, H. C.; Sherlock, S. (Royal Free Hosp., London NW3 2QG, England). *J. Clin. Pathol.* 30(8):704-708; 1977.

Serial serum alpha-fetoprotein determinations were carried out in 58 patients with acute liver damage to assess the value of this test as a marker of hepatocellular regeneration. One hundred sixty-three patients with chronic liver disease were also examined to determine whether this method of alpha-fetoprotein determination is of value in predicting the development of primary liver cell carcinoma. Using a radioimmunoassay technique, serum alpha-fetoprotein was detected in 50 healthy adults in concentrations of less than 20 μg/l. Among 44 patients with acute viral hepatitis, 43% exhibited a transient rise of serum alpha-fetoprotein, the peak occurring 8-9 days after the maximum recorded serum aspartate transaminase activity. Eight patients with paracetamol-induced liver injury were also shown to have transiently raised levels, the peak occurring earlier than in subjects with viral hepatitis. Six subjects with fatal fulminant hepatitis were studied; the three with the more protracted illness were noted to have increased levels before death. Twenty patients with chronic liver disease also had elevated serum alpha-fetoprotein concentrations (>20 μg/l, <500 μg/l). In four, primary liver cell cancer developed; in two of these the serum alpha-fetoprotein levels rose progressively, and in two it remained raised but at low levels. The observations in the patients with paracetamol-induced liver injury suggest a correlation between the degree of liver cell necrosis and subsequent alpha-fetoprotein production. The increase in serum alpha-fetoprotein in fulminant hepatitis may be related to the duration of illness regardless of the final outcome. Steadily increasing levels are highly suspicious of the development of primary liver cell carcinoma in patients with chronic liver disease.

1422 HBAg-POSITIVE CHRONIC LIVER DISEASE ASSOCIATED WITH CIRRHOSIS AND HEPATOCELLULAR CARCINOMA IN THE SENOI.

(Eng.) Sumithran, E.; Prathap, K. (Dept. Pathology, Univ. Malaya, Kuala Lumpur, Malaysia). *Cancer* 40(4):1618-1620; 1977.

To confirm the high incidence of primary hepatocellular carcinoma (PHC) among the Senoi, a Malaysian aborigine group, all tumors diagnosed by histologic examination of surgical and necropsy material from a local hospital over a 13-yr period were reviewed, and the presence of hepatitis B surface antigen (HBsAg) was assessed in paraffin sections of all livers from the necropsied cases. PHC was present in 10 of 22 Senoi patients with cirrhosis. All 22 livers contained hepatocytes that stained with Shikata's orcein stain and specific immunoperoxidase and immunofluorescent stains for HBAg. This observation raises the strong possibility that hepatitis B may be an important etiologic factor in the development of cirrhosis and PHC in the Senoi. The reason for the high susceptibility of the Senoi for hepatitis B virus infection is not clear, and the role of aflatoxin in the pathogenesis of PHC in the Senoi has yet to be determined. That the Senoi are a numerically small community, maintaining their own unique dietary and social customs and living in readily accessible areas in the Malaysian jungle, makes them an ideal population for the study of factors in the etiology of liver cancer.

1423 HEPATITIS-ASSOCIATED LIPID STORAGE MYOPATHY.

(Eng.) Patten, B. M.; Shabot, J. M.; Alperin, J.; Dodson, R. F. (Baylor Coll. Medicine, Houston, TX 77030). *Ann. Intern. Med.* 87(4):417-421; 1977.

The case of a 23-yr-old woman who developed severe myalgias in association with mild hepatitis B surface antigen-positive hepatitis is presented. Muscle biopsy showed myriads of microvacuoles filled with neutral lipid. Prednisone therapy (40 mg/day) was associated with complete clearing of all clinical and laboratory abnormalities. Since muscle carnitine levels were normal before treatment, it is concluded that infection with hepatitis virus may induce noncarnitine-deficient lipid storage myopathy in man.

1424 THE LIVER DURING AND AFTER FULMINANT HEPATITIS. (Eng.) Horney, J. T.; Galambos, J. T. (Emory Univ. Sch. Medicine, 69 Butler St., S.E., Atlanta, GA 30303). *Gastroenterology* 73(4): 639-645; 1977.

To study changes in liver histology during and after fulminant hepatitis, biopsies were obtained 5 to 14 days after onset of grade 3 or 4 coma, in 15 consecutive patients who recovered from fulminant hepatitis. In nine patients, follow-up biopsy was obtained 6 to 60 months after acute hepatitis, and autopsy was performed in two patients who died in 4 months from complications of hepatitis (aplastic anemia) or of corticosteroid therapy (sepsis). During fulminant illness, the biopsy findings were multilobular necrosis in four patients, confluent (bridging) necrosis in nine, and only portal inflammation in one. The duration or the grade of coma did not correlate with the severity of necrosis on the biopsy. Follow-up biopsy showed development of chronic (active) hepatitis in three of nine patients (with cirrhosis in one of these). Chronic liver disease was not found in the two autopsies. If fulminant hepatitis is the result of vigorous cell-mediated immune attack on hepatocytes, then this process cannot always eradicate chronic hepatitis B surface antigenemia, nor can it always prevent the development of chronic (active) hepatitis or cirrhosis.

1425 LIVER-SPECIFIC PROTEINS AND AUTOIMMUNITY IN INFLAMMATORY LIVER DISEASE. (Ita.) Alberti, A.; Realdi, G.; Bortolotti, F.; Trevisan, A.; Tremolada, F.; Rigoli, A. (Istituto di Medicina Clinica, Cattedra di Patologia Medica dell'Universita degli Studi di Padova, Padua, Italy). *Boll. Ist. Sieroter. Milan.* 55(5):411-425; 1976.

Cellular immune reactions against liver-specific proteins (LP$_1$) were studied by the leukocyte migration inhibition test in patients with different kinds of liver disease. Sixty-six percent of patients with chronic active hepatitis showed cellular immunity to LP$_1$. There was no difference in reactivity in patients who were serum positive for hepatitis B antigen (HBAg) and those who were HBAg-negative. Fifty-seven percent of patients with viral hepatitis B who tested in the acute phase of the disease had immunity to LP$_1$. After 6-12 months, only 17.8% of these same patients were still LP$_1$ positive Inhibition of leukocyte migration appears to decrease in these patients as virus is cleared from the liver. Inhibition of leucocyte migration was also found in 80% of HBAg-positive patients with chronic persistent hepatitis and in 23% of asymptomatic carriers of HBAg, most of whom progressed to cases of chronic active hepatitis. The cell-mediated immune response appears to play a major role in the pathogenesis of chronic active hepatitis. Infection with the hepatitis B virus must also be considered as a possible cause of autoimmune liver disease.

1426 LYMPHOCYTE POPULATIONS IN HBAg-POSITIVE ACUTE HEPATITIS. (Ita.) Bianchi, F. B.; Zauli, D.; Marchesini, G.; Gritti, F. M.; Fabbri, L.; Pisi, E. (Istituto Patologia Medica, Universita di Bologna, Bologna, Italy). *Minerva Gastroenterol.* 22(3):251-252; 1976.

T and B lymphocyte levels were determined in 11 patients with acute hepatitis and 21 patients with chronic uremia who were being treated with renal dialysis. All of the acute hepatitis patients and 11/21 uremia patients were seropositive for hepatitis B antigen (HBAg). There was a significant reduction in the numbers of circulating lymphocytes and monocytes in all HBAg-positive patients. The absolute numbers and the percentage of circulating B lymphocytes increased from 674 ± 120 cells/cm^3 or 27.0 ± 4.0% in controls to 885 ± 303 cells/cm^3 or 42.7 ± 9.6% in hepatitis patients; the increase in absolute number was not significant, whereas the percentage increase was significant ($p<0.001$). The absolute number and percentage of circulating T lymphocytes decreased significantly in all patients, especially in HBAg-positive uremia patients in whom values fell from 1,567 ± 428 cells/cm^3 or 65.5 ± 8.0% in the controls to 844 ± 434 cells/cm^3 or 45.6 ± 15.3%. The lymphopenia that occurs in the early stages of viral hepatitis is the result of a reduction in the number of circulating T lymphocytes. This reduction in the uremia patients is a reflection of the inhibitory action of uremia on the immune response.

1427 HUMORAL AND CELLULAR IMMUNE REACTIONS AGAINST HBsAg AND AGAINST LIVER-SPECIFIC PROTEINS IN THE COURSE OF ACUTE AND CHRONIC HEPATITIS. (Ita.) Realdi, G.; Alberti, A.; Bortolotti, F.; Tremolada, F.; Diodati, G.; Cadrobbi, P. (Clinica Medica Generale dell'Universita di Padova, Padova, Italy). *Minerva Gastroenterol.* 22(3):207-212; 1976.

Cell-mediated immunity against liver specific protei (LSP) and hepatitis B surface antigen (HBsAg) was studied by means of the leukocyte migration inhibition test in 80 patients and 20 control subjects. Twenty-two patients had acute viral hepatitis B (AVHB), 12 had chronic persistent hepatitis (CPH), 15 had chronic active hepatitis (CAH) and were seropositive for hepatitis B antigen (HBAg), 16 had CAH and were HBAg-negative, and 15 had alcoholic cirrhosis. LSP was found in 54%, 53%, 75%, and 16% of patients with AVHB, (HBAg-positive) CAH, (HBAg-negative) CAH, and CPH, resp. Cirrhotic patients an controls were LSP-negative. In CAH patients treated with prednisone, there was a reduction in the autoimmune response, while untreated patients remained

SP-positive over a 12-month period. Although 50%
f AVHB patients were LSP-positive in the acute
hase of their disease, only 10% were still positive
-12 months later. Thirty-one percent of HBAg-
ositive CAH patients exhibited cellular immunity
o HBsAg. In the acute disease phase, 51% of AVHB
atients had cell-mediated immunity to HBsAg; cel-
ular immunity appeared in 83% after 3 months and
n 58% after 12 months. Antibody (Ab) to HBsAg in
hese patients was low in the acute phase, but
limbed steadily from 3-12 months, by which time
0% were HBsAb positive. The autoimmune reaction
o LSP in AVHB patients is most likely a result of
embrane protein alteration by the virus. Sensi-
ivity to LSP is limited and disappears with the
learance of the virus from the body. In HBAg-
ositive CAH patients, the virus persists in the
ody, and autoimmunity to LSP persists also. HBAg-
egative CAH is a classic autoimmune disease, which
ay be initiated by viruses, drugs, or other ex-
ernal agents; cell-mediated immunity to HBsAg in
his disease suggests previous contact with the HB
irus in some patients. It is also suggested that
element of genetic predisposition to this auto-
mune disease may exist.

28 CORRELATION BETWEEN TITER OF ANTIBODY TO HEPATITIS B CORE ANTIGEN AND PRESENCE VIRAL ANTIGENS IN THE LIVER.

(Eng.) Kojima,
; Udo, K.; Takahashi, Y.; Yoshizawa, H.; Tsuda,
; Itoh, Y.; *et al.* (Gifu Prefectural Hosp.,
fu-ken, Japan). *Gastroenterology* 73(4):664-667;
77.

an effort to find a reliable indicator of per-
stent hepatitis B virus (HBV) infection, markers
HBV infection in the serum were correlated with
e presence of both hepatitis B core antigen
BcAg) and hepatitis B surface antigen (HBsAg) in
e livers of 31 autopsied patients with liver
rrhosis. Liver specimens were stained for HBcAg
d HBsAg by the direct immunofluorescence method.
l specimens had detectable levels of antibody to
cAg (anti-HBc). Their premortem serum samples
re tested for HBsAg, antibody to HBsAg (anti-HBs),
d anti-HBc. Persistent (HBV) infection, as
dged by circulating and/or liver hepatitis B
tigens, was identified in 18 patients, and all of
em revealed a high titer of anti-HBc ranging from
^{1} to 2^{16} by the immune adherence hemagglutina-
on method. In contrast, the anti-HBc titer of
e remaining 13 patients without detectable HB
tigens, was less than 2^{9}, and the geometric mean
ter of anti-HBc of the patients with persistent
infection was significantly higher than that of
e patients without (13.9 ± 1.55 versus 7.23 ±
0; *t* test, $p<0.001$). A combination of circu-
ting anti-HBs and hepatic HB antigens was found
one patient, whose serum revealed an anti-HBc
ter of 2^{12}. A high titer of anti-HBc in the
rum (immune adherence hemagglutination titer $\geq 2^{11}$)
ems to be a reliable indicator of persistent
infection in the liver.

29 EXPRESSION OF HEPATITIS B VIRUS-SPECIFIC MARKERS IN ASYMPTOMATIC HEPATITIS B SURFACE ANTIGEN CARRIERS.

(Eng.) Hess, G.; Arnold, W.; Shih, J. W. K.; Kaplan, P. M.; Purcell, R. H.; Gerin, J. L.; *et al.* (Second Dept. Internal Medicine, Univ. Mainz, 6500 Mainz, W. Germany). *Infect. Immun.* 17(3):550-554; 1977.

The state of hepatitis B virus infection was assessed in 22 asymptomatic hepatitis B surface antigen (HBsAg) carriers. The presence of serum hepatitis B e antigen (HBeAg) was closely associated with serum HBsAg-specific DNA polymerase activity, hepatitis B core antigen (HBcAg) in serum and liver cell nuclei, and a histological picture of chronic hepatitis. No HBsAg-specific DNA polymerase activity or HBcAg was detected in highly concentrated sera positive for antibody to HBcAg. In addition, liver biopsy specimens from carriers with antibody to hepatitis B e antigen (anti-HBe) were negative for HBcAg by immunofluorescence, and the liver histology was either normal or revealed only fatty changes. These data indicate that the anti-HBe-positive sera contained either no Dane particles or, if present, at least a 500-fold lower concentration of Dane particles than that found in HBeAg-positive sera.

1430 A DIRECT IMMUNOFLUORESCENCE METHOD FOR THE DETECTION OF HEPATITIS B CORE ANTIGEN IN FORMALIN-FIXED AND GELATIN-EMBEDDED LIVER SPECIMENS.

(Eng.) Yoshizawa, H.; Itoh, Y.; Akahane, Y.; Tsuda, F.; Miyakawa, Y.; Mayumi, M. (Tokyo Metropolitan Inst. Medical Science, Bunkyo-ku Tokyo 113, Japan). *J. Clin. Pathol.* 30(8):776-778; 1977.

A simple method for detecting hepatitis B core antigen (HBcAg) in formalin-fixed liver specimens by direct immunofluorescence is reported. Liver tissue was obtained at necropsy from patients with various hepatic diseases and was fixed and stored in 10% formalin. The specimens are washed free of formalin in tap water for 12 hr and incubated in distilled water containing 0.01% NaN_3 and 5% gelatin at 37 C for 12 hr, and successively in water supplemented with 10% gelatin at 37 C for 4 hr. The specimens are transferred to a Petri dish filled with 10% gelatin at 37 C, and the dish is allowed to consolidate at room temperature. The specimens are then snap-frozen in n-hexane. In one specimen from a patient with liver cirrhosis, HBcAg-positive immunofluorescence was exclusively localized in the nucleus. About 80% of the hepatocytes were positive with a clear bright fluorescence and virtually no background staining. The staining of hepatitis B surface antigen (HBsAg) was localized in the cytoplasm, and no nuclear fluorescence was observed. The detectability of both HBcAg and HBsAg by the direct immunofluorescence method was similar in fixed and unfixed specimens embedded in gelatin. The basis for the success of this method is apparently the embedding process, with which the dehydration process for embedding in paraffin is avoided.

1431 SOLID PHASE RADIOIMMUNOASSAY FOR QUANTITATING ANTI-HBs IN HEPATITIS B IMMUNE

GLOBULIN. (Eng.) Ratliff, E. A.; Pollack, W.; Tripodi, D.; Ho, T. (Ortho Res. Inst. Medical Sciences, Raritan, NJ 08869). *Int. Arch. Allergy Appl. Immunol.* 54(3):231-237; 1977.

A solid-phase radioimmunoassay technique was modified to quantitate the antibody in hepatitis B immune globulin. This procedure allows the data to be resolved into a Sips adsorption isotherm. This treatment of data permits the total antibody, intrinsic average binding constant, and index of heterogeneity to be determined, since it was demonstrated that the antibody behaves as if it is monovalent with respect to binding its antigen. Two assay procedures based upon different methods of measuring nonspecific binding are described. In the first, a labeled control globulin known to be free of antibody to hepatitis B surface antigen is used. In the second assay procedure, buffer-treated tubes are used as the "negative" control. The methods were found to give indistinguishable results, but the authors believe that the latter will offer the greatest utility.

1432 PRESENCE OF HBsAg AND IgG ON THE LIVER CELL MEMBRANE IN PATIENTS WITH ACUTE AND CHRONIC HEPATITIS. (Ita.) Alberti, A.; Realdi, G.; Tremolada, F.; Rigoli, A. M.; Fattovich, G.; Spina, G. P. (Clinica Medica Generale, Univ. Padova, Padua, Italy). *Minerva Gastroenterol.* 22(3):235-240; 1976.

The presence of the hepatitis B antigen (HBAg) and IgG on the surface of hepatocytes from patients with acute and chronic hepatitis was determined by immunofluorescence. Ten patients with acute hepatitis B were examined during the first week of illness. Seven of these 10 had HBAg at the cell surface and 5/10 had intracellular HBAg. An additional 13 patients with acute hepatitis B were examined during the recovery phase of the disease. None of these patients had HBAg on the cell surface, but 33% of them had intracellular HBAg. Five patients with chronic persistent hepatitis B were studied also. Two of these five were seropositive for HBAg. One of the seropositive patients had intracellular HBAg. Fifteen patients with chronic active hepatitis (CAH) were also studied. Eight patients were seropositive and seven were seronegative for HBAg. All of the positive patients had HBAg located within the cell but not at the cell surface. None of the seronegative CAH patients had intracellular IgG. Surface IgG was found in 10% of the acute hepatitis B patients examined in the first week of the study and 7.6% of these examined in the recovery phase; 75% of the seropositive and 57% of the seronegative CAH patients also had surface IgG. All of the other patients were negative for surface IgG. Five patients with alcoholic cirrhosis and 4 normal controls were negative for both HBAg and IgG at both locations. These results suggest that in patients with acute hepatitis B, cellular immune reactions are perhaps responsible for cell lysis and the elimination of both infected cells and the antigenic organism. In CAH patients, cellular antibodies are probably directed against diverse antigens.

1433 e ANTIGEN AND ANTIBODY IN OUTBREAKS OF HEPATITIS B IN TWO RENAL DIALYSIS UNITS. (Eng.) Gibson, P. E. (Central Public Health Lab., Colindale Ave., London NW9 5HT, England). *J. Clin. Pathol.* 30(8):717-719; 1977.

In two renal dialysis units that had outbreaks of hepatitis B, patients were studied for the presence of e antigen and antibody. In one unit, in which the illness was mild and most of the 27 patients (78%) became carriers of hepatitis B surface antige (HBsAg), all but one patient had e antigen. Most of the HBsAg carriers had persisting e antigen, and most of the transient patients had also transient e antigen. In the other unit, in which the illness was more severe, none of the 10 patients became a carrier. Only 30% had e antigen during the acute phase of illness and 40% developed anti-e just before clearing HBsAg. The differences between these two units may reflect strain differences in the infectivity of hepatitis B virus.

1434 HEPATITIS B e ANTIGEN AND ANTIBODY ACTIVITY IN HEPATITIS B VIRUS INFECTION. (Eng.) Tiku, M. L.; Makhdoomi, G. M.; Beutner, K. R.; Nath, N.; Ogra, P. L. (Children's Hosp., 219 Bryant St., Buffalo, NY 14222). *J. Pediatr.* 91(4): 540-544; 1977.

Groups of institutionalized subjects, volunteer blood donors with serologic evidence of asymptomati hepatitis B virus infection, and patients with acut type B viral hepatitis were studied for the presence of hepatitis B e antigen (HBeAg) and antibody (anti-HBe) in a sequential manner over 2-3 yr. HBeA was detected in 9.5% of 226 institutionalized residents and 105 volunteer blood donors and in 24% of 46 patients with acute type B viral hepatitis. HBeAg-positive subjects frequently had persistently elevated SGPT levels. Anti-HBe activity was observ in 26% to 32% of subjects positive for hepatitis B surface antigen (HBsAg). Long-term follow-up indicated that HBsAg-positive subjects with anti-HBe did not eventually become seronegative for HBsAg.

LIVER AND BILIARY TRACT

Chronic Hepatitis

1458 CLINICAL SIGNIFICANCE OF SERUM COMPLEMENT IN CHRONIC LIVER DISEASE AND ACUTE HEPATIC INSUFFICIENCY. (Ita.) Naccarato, R.; Farini, R.; Chiaramonte, M.; Meani, A.; Giordano, C.; Gritti, G. (Clinica Medica I, Universita degli Studi, Padova, Italy). *Minerva Gastroenterol.* 22(3):213-218; 1976.

Serum levels of two complement fractions, C3 and C4, were determined in a series of patients with various acute and chronic liver diseases. The C3 fraction of complement was much lower in patients with massive liver necrosis, chronic active hepatitis (CAH) with cirrhosis, cirrhosis with and without ascites, and cirrhosis after portacaval anastomosis than in normal controls. In patients with primary bilateral cirrhosis (CPB) however, C3 levels were much higher than control values. In patients with CAH without cirrhosis, C3 levels were not appreciably different from the control levels. In CAH patients, there was no correlation between C3 levels and serum levels of antibodies and immunoglobulins but there was a significant correlation between C3 levels and pseudocholinesterase levels. In patients with CPB, there was a correlation between C3 levels and alkaline phosphatase levels but not between C3 levels and bilirubinemia. There was no correlation between C3 levels and any immunological indicators. C4 levels paralleled C3 levels in all patients. There was no evidence that complement was used in the formation of immunological components in the blood. It is concluded that C3 and C4 levels cannot be used to follow the immune response in CAH patients and that the significance of C3 and C4 levels in CPB patients cannot be determined from these studies.

1459 EVALUATION OF CELLULAR IMMUNITY BY SKIN TEST IN CHRONIC HEPATITIS AND LIVER CIRRHOSIS. (Ita.) Savorani, G.; Sarti, G. (Ospedale Provinciale Specializzato M. Malpighi, Bologna, Italy). *Boll. Soc. Ital. Biol. Sper.* 52(12):859-865; 1976.

Cellular immunity in terms of sensitivity to dinitrochlorobenzene (DNCB) and reaction to five intradermal skin tests were measured in 6 patients with chronic aggressive hepatitis (CAH), 9 patients with chronic persistent hepatitis (CPH), and 45 patients with cirrhosis. Twelve of the cirrhosis patients were classified as "compensated" and 33 were classified as "noncompensated." Eight of 9 CPH patients, 4 of 6 CAH patients, 8 of 12 "compensated" cirrhosis patients, and 9 of 23 "noncompensated" cirrhosis patients were DNCB-positive. Nine of 9 CPH patients, 5 of 6 CAH patients, 12 of 12 "compensated" cirrhosis patients, and 24 of 33 "noncompensated" cirrhosis patients were positive for at least one of the five intradermal tests. All 29 DNCB-positive patients were also positive for at least one intradermal test. Of the 31 DNCB-negative patients, 21 were positive for at least one intradermal test while 10 were both DNCB negative and intradermal test negative. Of these 10 patients, 8 were "noncompensated" cirrhosis patients and one was a CAH type B patient. Cellular immunity remains generally intact in CPH patients and in patients with moderate cases of CAH. Cirrhosis patients first lose the ability to respond to new antigens and then the capacity to recognize an antigen with which they have had previous contact. There appears to be a correlation between a deficiency in cellular immunity and the type and phase of liver disease. DNCB appears to be a more sensitive indicator of this deficiency than are intradermal skin tests.

1460 AUTOIMMUNITY IN CHRONIC ACTIVE HEPATITIS AND DIABETES MELLITUS. A REVIEW. (Eng.) Galbraith, R. M.; Fudenberg, H. H. (Medical Univ. South Carolina, Charleston, SC 29401). *Clin. Immunol. Immunopathol.* 8(1):116-149; 1977.

Current evidence for the occurrence of autoimmunity in chronic active hepatitis and diabetes mellitus is reviewed. In addition, factors of potential importance in the initiation and perpetuation of these potentially damaging reactions are discussed in relation to the genetics of these disorders. The development of techniques for examining cellular immunity, particularly the leukocyte migration test, made the search for evidence of organ-specific immunity in chronic active hepatitis possible. Leukocyte inhibitory factor production has been measured in most studies, but a number of different antigens have been used. The major difficulty in these studies has been in establishing vital cultures of normal adult hepatocytes, although diseased liver tissue from patients with alcoholic liver disease has been successfully established in long-term culture. Progress in the investigation of humoral immunity to lipoprotein derived from the cell membrane (LP-I) has lagged behind that of cellular responses, since the demonstration of liver-specific antibodies in the serum of patients with chronic active hepatitis is more difficult. One investigator has used a passive hemagglutination technique to detect antibodies to liver-specific protein, the antigens used being a mixture of LP-I and a smaller cytoplasmic antigen, LP-II. Human studies demonstrating evidence of organ-specific autoimmunity in chronic active hepatitis have been reinforced by a number of animal experiments. In one case, chronic hepatitis was successfully induced in rabbits by means of repeated injections of human and rabbit liver-specific protein in complete Freund's adjuvant. The accumulation of evidence of autoimmune reactions in diabetes mellitus has in many respects run parallel to that in chronic active hepatitis. Antibodies directed against crude homogenates of pancreas including exocrine tissue were first described in 1960.

1461 HLA AND CHRONIC ACTIVE HEPATITIS. (Eng.) Mazzilli, M. C.; Trabace, S.; DiRaimondo, F.; Visco, G.; Gandini, E. (Cattedra di Genetica Medica, Universita degli Studi di Roma, Ospedale L. Spallanzani, Via Portuense, 292 Roma, Italy). *Digestion* 15(4):278-285; 1977.

Histocompatibility antigen (HLA) typing (24 alleles of the A and B loci) was performed in 42 patients with chronic active hepatitis (CAH). The criteria used for diagnosis were (a) histological profile of CAH, (b) SGOT transaminase levels above 50 mU/ml, (c) serum γ-globulin above 2 g% or at least two positive immunologic tests, and (d) clinical course lasting at least 180 days or cirrhosis evident at biopsy. An increased frequency of HLA-A3 was observed (47.6% compared to 19.1%) in 266 healthy controls. The phenotype association A3/Bw35 also was increased (28.5% in the CAH groups compared to 6.0% in controls). HLA typing was performed in seven families of seven A3/Bw35 CAH patients. In five of the families, the A3/Bw35 haplotypic segregation was proven. The data in this study indicate that the HLA phenotype is a marker of a dominant susceptibility to the disease.

1462 HLA IN DIFFERENT FORMS OF CHRONIC ACTIVE HEPATITIS. A COMPARISON BETWEEN ADULT PATIENTS AND CHILDREN. (Eng.) Freudenberg, J.; Baumann, H.; Arnold, W.; Berger, J.; Meyer zum Buschenfelde, K. H. (Blutspendedienst des DRK-Landesverbandes Rheinland-Pfalz Burgweg 5-7, D-6550 Bad Kreuznach, Mainz, W. Germany). *Digestion* 15(4): 260-270; 1977.

The presence or absence of hepatitis B surface antigen (HBsAg) and autoantibodies (AutoAb) were measured and correlated with histocompatibility antigens (HLA) in 108 adult patients and 34 children with chronic active hepatitis (CAH). All patients had the morphological profile typical of CAH and clinical and biochemical signs of high inflammatory activity of at least 6-months duration. Patients were divided into four groups: (1) AutoAb-positive and HBsAg-negative (probably causing an autoimmune type of CAH), (2) AutoAb-negative and HBsAg-negative (pathogenic mechanism unknown but may be a nonhepatitis B virus), (3) HBsAg-positive and AutoAb-negative, and (4) HBsAg-positive and AutoAb-positive (most likely caused by hepatitis B virus). The distribution of HLA among the four groups showed no statistically significant differences. When HLA levels in these groups were compared with controls, an increased frequency of HLA-B8 and HLA-A_1 was noted in the autoimmune type of CAH (group 1). The relative risk for HLA-B8-positive adults to get an autoimmune hepatitis is 19.6, compared to 7.0 in children, and 15.4 in combined groups. No other significant deviation of HLA antigens for the different types of CAH was observed.

1463 CHANGES IN LABORATORY PARAMETERS IN LIVER DISEASE PATIENTS AFTER TREATMENT WITH TOXEPASE COMPLEX. (Ita.) Lenzi, S. (I Istituto di Patologia Speciale Medica e Metodologia Clinica, Universita di Bologna, Bologna, Italy). *Minerva Med.* 67(46):2961-2974; 1976.

Twenty patients with liver disease (9 with chronic aggressive hepatitis [CAH], 2 with chronic persisting hepatitis [CPH], and 9 with cirrhosis) were treated with Toxepase complex, which consists of uridine-5-diphosphoglucose, glutathione, and vitamin B_{12}. Treatment was evaluated by determining LDH, glutamic acid dehydrogenase, alkaline phosphatase, γ-glutamyl transpeptidase, and nonspecific cholinesterase activities. These enzyme activities can indicate cellular necrosis, cholestasis, and impaired protein synthesis. Two weeks after the initiation of treatment, the serum levels of these enzymes decreased, indicating a return to normal liver function in the patients. This return to normal levels occurred in all patients and was most apparent in those with CAH and cirrhosis. CPH patients benefited least from treatment. Toxepase complex appears to be useful in the treatment of CAH and liver cirrhosis.

LIVER AND BILIARY TRACT

Alcoholic Liver Disease

1471 IDIOPATHIC HEMOCHROMATOSIS AND IRON OVERLOAD IN ALCOHOLIC LIVER DISEASE: DIFFERENTIATION BY HLA PHENOTYPE. (Eng.) Simon, M.; Bourel, M.; Genetet, B.; Fauchet, R.; Edan, G.; Brissot, P. (Hopital Pontchaillou, 35043 Rennes, France). *Gastroenterology* 73(4):655-658; 1977.

Histocompatibility antigens (HLA) A and B were determined in 38 patients with idiopathic hemochromatosis (IH) and 22 patients with iron overload accompanying alcoholic liver disease (AH). As previously described, HLA A3 and HLA B14 antigens appeared more frequently in the IH group (76.3% and 28.9%, resp.) than in 204 controls (27% and 3.4%). In the AH group, the frequency of A3 (22.7%) and B14 (13.6%) was not significantly different from that observed in controls. The frequency of A3 was significantly lower in the AH group than in the IH group ($p<0.0001$). On this basis, a clear difference appears between the two conditions with iron overload, and genetic analysis of the results ruled out the hypothesis that AH would be a heterozygous form of IH exposed by alcohol.

1472 EARLY PERIVENULAR SCLEROSIS IN ALCOHOLIC FATTY LIVER: AN INDEX OF PROGRESSIVE LIVER INJURY. (Eng.) Van Waes, L.; Lieber, C. S. (Bronx Veterans Admin. Hosp., 130 West Kingsbridge Rd., Bronx, NY 10468). *Gastroenterology* 73(4):646-650; 1977.

To determine whether perivenular sclerosis, found in heavy drinkers with fatty liver, could be a precursor lesion of cirrhosis, controlled studies were performed in animal models and in humans. In alcohol-fed baboons that developed fibrosis or cirrhosis, progressive perivenular sclerosis invariably started at the fatty liver stage before or, even more commonly, in the absence of alcoholic hepatitis. No sclerosis occurred in controls or in alcohol-fed baboons and rats that did not progress beyond the fatty liver stage. Thirty of 75 patients who were heavy drinkers and had fatty liver (without other alcohol-induced liver changes) had a rim of fibrous tissue around the terminal hepatic venules that stained for collagen. None of 20 age-matched, nonalcoholic controls had sclerosis. In five controls who consumed moderate amounts of alcohol (36-43% of total caloric intake) for up to 4 weeks, fatty liver developed, but perivenular sclerosis did not. The clinical and experimental data indicate that sclerosis around the terminal venules, a common but often overlooked complication of alcoholic fatty liver, reflects heavy prolonged drinking, and may identify those patients who are susceptible to develop the more advanced lesions of alcoholic liver injury upon continued drinking.

1473 TESTICULAR AND SPERMATOZOAL AUTOANTIBODY IN CHRONIC ALCOHOLIC MALES WITH GONADAL FAILURE. (Eng.) Van Thiel, D. H.; Gavaler, J. S.; Smith, W. I.; Rabin, B. S. (Univ. Pittsburgh Sch. Medicine, Pittsburgh, PA 15261). *Clin. Immunol. Immunopathol.* 8(2):311-317; 1977.

To determine whether immunity plays a part in the development or perpetuation of alcoholic gonadal injury, sera from 40 chronic alcoholic men, whose liver histology was classified by biopsy, were examined for the presence of autoantibodies utilizing a panel of tissue antigens. The frequency of autoantibodies detected in the alcoholic men was compared with that observed in 450 control men. Antibody only to spermatozoa and testicular antigens was detected in the alcoholic men at an increased frequency ($p \leq 0.001$). The reproductive function of the testes was evaluated in the alcoholic men. Of 22 alcoholic men requested to collect an ejaculate for evaluation, only 5 were potent enough to obtain a specimen for analysis. Two of these five alcoholic men were azoospermic and one was consistently oligospermic. All nine alcoholic men subjected to testicular biopsy demonstrated seminiferous tubular atrophy. Autoimmunity may play a role in the development or perpetuation of the observed gonadal failure present in alcoholic men.

1474 LIPOLYSOSOMES IN HUMAN LIVER: DISTRIBUTION IN LIVERS WITH FATTY INFILTRATION. (Eng.) Hayashi, H.; Winship, D. H.; Sternlieb, I. (Univ. Missouri Medical Center, Columbia, MO 65201). *Gastroenterology* 73(4):651-654; 1977.

The hepatocytes of 14 randomly selected patients with liver diseases were examined for the presence of lipolysosomes (lysosomes containing large lipid droplets). Organelles that displayed the same morphological characteristics and enzymatic activity as those originally described in the hamster and those found in the hepatocytes of patients with Wolman's or Wilson's disease were also found in hepatocytes of 13 of the 14 biopsy specimens that showed minimal to severe fatty infiltration. The numbers and sizes of the lipolysosomes seemed to increase with the degree of fatty infiltration, while their proportion in relation to the total number of lipid droplets remained below 5%. Lysosomes probably play an important role in hepatic lipid metabolism, and various pathogenetic mechanisms may trigger their proliferation.

1475 SERUM 25-HYDROXYVITAMIN D_3 LEVELS IN PATIENTS WITH LIVER DISEASE. (Eng.) Sonnenberg, A.; von Lilienfeld-Toal, H.; Sonnenberg, G. E.; Rohner, H. G.; Strohmeyer, G. (Stadtspital Triemli, Birmensdorferstr. 497, CH-8063 Zurich, Switzerland). *Acta Hepatogastroenterol.* 24(4): 256-258; 1977.

Serum 25-hydroxyvitamin D_3 levels were determined in 45 patients with chronic liver diseases by a radioreceptor assay and correlated with the serum albumin, calcium, and inorganic phosphate levels. The serum calcium level in the patients (4.4 ± 0.4 mEq/l) was significantly lower than that in 50 healthy controls (4.8 ± 0.2 mEq/l, $p<0.001$). The inorganic phosphate level in the patients (1.6 ± 0.3 mEq/l) was significantly lower than that in the controls (2.2 ± 0.4 mEq/l, $p<0.001$), but there was no significant correlation between the calcium level and the albumin or transaminase levels. The results indicate that 25-hydroxylation occurs mainly in the liver and that vitamin D absorption is impaired following liver injury.

1476 HEPATIC XENON-133 RETENTION: A NON-INVASIVE DIAGNOSTIC TEST FOR STEATOSIS [Abstract]. (Eng.) Ahmad, M. L.; Perrillo, R. P.; Sunwoo, Y. L.; Donati, R. M. (St. Louis Veterans Admin. Hosp., St. Louis, MO). *Gastroenterology* 73(5):1211; 1977.

1477 ENDOTOXIN AND BACTERIA IN PORTAL BLOOD [Letter to Editor]. (Eng.) Ansell, J.; Widrich, W.; Johnson, W.; Fine, J. (Veterans Admin. Hosp., Boston, MA 02130). *Gastroenterology* 73(5): 1190; 1977.

1478 THE COMPARATIVE SURVIVALS OF ALCOHOLICS VERSUS NONALCOHOLICS AFTER DISTAL SPLENORENAL SHUNT [Abstract]. (Eng.) Levi, J. U.; Zeppa, R.; Hutson, D. G.; Schiff, E.; Livingstone, A.; Fink, P. (Univ. Miami Sch. Medicine, Miami, FL 33152). *Gastroenterology* 73(5):1231; 1977.

1479 SERUM TRIIODOTHYRONINE (T_3) AS AN INDEX OF SEVERITY AND PROGNOSIS IN ALCOHOLIC LIVER DISEASE (ALD). EFFECT OF PROPYLTHIOURACIL (PTU) [Abstract]. (Eng.) Kalant, H.; Orrego, H.; Israel, Y.; Walfish, P. G.; Rankin, J.; Findlay, J. (Addiction Res. Foundation of Ontario, Toronto, Ontario, Canada). *Gastroenterology* 73(5):1227; 1977.

LIVER AND BILIARY TRACT

Cirrhosis

1486 THE LAPAROSCOPIC STAGING OF PRIMARY BILIARY CIRRHOSIS. (Eng.) Lindner, H.; Dammermann, R.; Kloppel, G. (German Red Cross Hosp., Hamburg, W. Germany). *Endoscopy* 9(2):68-73; 1977.

The laparoscopic photographs of 38 cases of primary biliary cirrhosis with high mitochondrial antibody titers were reviewed to see if these photographs could be used as the basis of a system of laparoscopic staging. By scrutinizing the photographs taken with the Lumina photolaparoscope and reviewing the histological findings, the liver disease was divided into four stages: stage 1, nonspecific reactive hepatitis and yellowish-red coloration of the liver; stage 2, accentuation of yellowish-red pattern, increased signs of mesenchymal activity with conspicuous arterial vascularization and lymphatics, and granulomas and splenomegaly; stage 3, liver surface assumes a granular appearance with accentuation of the hexagonal lobule structure, but lobular regeneration is absent (the first signs of portal hypertension are recognizable); stage 4, development of nodularity on the liver surface and of a deepening greenish-blue color in advanced cases. Portal hypertension and decompensation are obvious features of this disease. However, by laparoscopy alone it is not possible to distinguish pure primary biliary cirrhosis from its mixed forms with chronic active hepatitis. It is suggested that intravital macropathology as revealed by the laparoscope is a valuable supplement to liver biopsy in the diagnosis and staging of primary biliary cirrhosis.

1487 EPIDEMIOLOGY OF CHRONIC LIVER DISEASES. (Eng.) Jorke, D.; Reinhardt, M. (Stadtisches Krankenhaus Jena, Dornburger Str. 159, DDR-69 Jena, E. Germany). *Acta Hepatogastroenterol.* 24(4):220-225; 1977.

The frequency and distribution of chronic liver diseases were studied in the East German population. In East Germany, mortality from liver cirrhosis decreases, in contrast to most other countries, although alcohol consumption is continuously increasing. In Berlin and in the industrialized districts, mortality from cirrhosis is higher than in the rural areas. Within a period of 6 yr, the number of inpatients with chronic liver diseases has risen from 11,600 to 14,200. From the epidemiologic point of view, viral hepatitis is not the main source of liver cirrhosis. The total recovery rate for acute hepatitis has increased from 80% to 94% over a period of 8 to 10 yr; liver cirrhosis was found to have developed only in 0.3%. Seventy percent of cirrhotic patients never suffer from viral hepatitis. Seventy-three percent of 1.8 million blood donors that were subjected to SGPT and hepatitis B surface antigen screening tests showed histologic changes of the liver. Using these screening methods it has been possible to register 7% of the persons among these blood donors as having liver diseases. Early recognition and treatment of chronic liver diseases seem to result in a reduction of mortality from liver cirrhosis.

1488 TOTAL FATTY ACIDS OF HUMAN LIVER IN RELATION TO AGE, SEX AND PATHOLOGY. (Eng.) Gershbein, L. L.; Baburao, K.; Pedroso, A. F. (Northwest Inst. Medical Res., 5656 W. Addison St., Chicago, IL 60634). *Acta Hepatogastroenterol.* 24(4):250-255; 1977.

Fatty acid composition was determined in lipids extracted from 28 normal, 3 fatty, and 2 cirrhotic adult livers removed at necropsy as well as from 4 newborn and infant organs. The total fatty acids were processed, the methyl esters submitted to gas chromatographic analysis, and the acid differences ascertained relative to age, sex, and pathology. The levels of unsaturated acids ranged higher than those of the saturated homologs and were even greater in the fatty liver lipids. The latter showed an increase in 18:1 and depressions in 18:0, 22:0, and 24:0 as compared with the normal specimens and the same changes in 18:0 and 18:1 as compared with the cirrhotic lipids.

1489 STUDY OF HEPATIC PORPHYRINS IN PATIENTS WITH LIVER CIRRHOSIS.

(Spa.) Enriquez De Salamanca, R.; Solis Herruzo, J. A.; Arnalich, F.; Pardo Rueda, J. (Instituto de Medicina Experimental del C.S.I.C., Madrid, Spain). *Rev. Esp. Enferm. Apar. Dig.* 47(6):805-808; 1976.

Among 2,286 liver biopsy samples observed under UV light, 52 showed the red fluorescence (F+) characteristic of porphyria cutanea tarda (PCT), yet only 38/52 patients had dermal lesions and clinical symptoms of PCT. The remaining 14 F+ patients had chronic hepatopathies. Levels of the hepatic porphyrins (uro-, hepta-, hexa-, penta-, copro-, and protoporphyrin) in liver samples from seven F+ PCT patients and ten F+ hepatopathy patients were assessed by electrophoresis. Results were compared with those obtained in 20 patients with normal livers, 15 cirrhotic patients (F-), 6 patients with hepatic tumors, and 6 with cholestasis due to biliary obstruction. Total porphyrin levels were higher in the tissues of all 17 F+ patients than in normal tissues: 387 ± 119 µg/100 g for F+ patients without PCT, 5,935 ± 3,748 µg/100 g for F+ PCT patients versus 84 ± 31 µg/100 g for patients with normal livers. Total porphyrin levels were 140 ± 54 µg/100 g in F-cirrhosis patients, 372 ± 85 µg/100 g in patients with primary liver tumors, and 247 ± 73 µg/100 g in cholestasis patients. There was a higher proportion of uro- and heptaporphyrin in PCT liver tissue than in F+ non-PCT tissue. In the tumor tissue and cirrhosis F- and cholestasis tissues, protoporphyrin, and coproporphyrin predominated. The proportion of the different porphyrins was similar in all F- tissues to the proportion of porphyrin in normal tissue, whereas the proportions in both F+ groups were different from that in normal tissue. The similarities among the accumulated porphyrins in PCT patients and F+ chronic hepatopathy patients suggest that the same metabolic error may play a role in both disorders.

1490 ELECTROPHORETIC ANALYSIS OF URINARY PORPHYRINS IN HEPATIC CIRRHOSIS.

(Spa.) Solis Herruzo, J. A.; Enriquez de Salamanca, R.; Pardo Rueda, J.; Arnalich, F. (Instituto de Medicina Experimental del C.S.I.C., Madrid, Spain). *Rev. Esp. Enferm. Apar. Dig.* 47(6):813-816; 1976.

The urine of 25 cirrhotic patients was analyzed to determine the incidence of porphyria cutanea tarda (PCT) in patients without the dermatological symptoms of this disease and the results were compared with those from 50 patients with PCT and 30 normal controls. Seventeen of the 25 cirrhotic patients had a marked history of alcoholism, 2 were Australia antigen positive, and 6 others were lacking these etiological factors. The uro-, hepta-, hexa-, penta-, and coproporphyrin fractions in the urine were separated by electrophoresis. A Doss index of PCT >14/100 indicated a carrier of the metabolic error of PCT. Eight of the cirrhotic patients had a pathologic PCT index. Such an anomaly in the electrophoretic pattern of the urinary porphyrins was confirmed by fluorescence tests; hepatic tissue gave a red fluorescence and had elevated levels of uro- and heptaporphyrins (54.5 ± 18.9 µg/day and 18 ± 10 µg/day, resp., versus 9 ± 7 µg/day and trace amounts, resp., in normal controls). No correlation was evident between the degree of the hepatopathy and the urinary pattern of the porphyrins. The metabolism of the porphyrins may be genetically altered in many of the patients, and this alteration may manifest itself in many ways, one of which is hepatopathy.

1491 THE CONVERSION OF D-XYLOSE INTO D-THREITOL IN PATIENTS WITHOUT LIVER DISEASE AND IN PATIENTS WITH PORTAL LIVER CIRRHOSIS.

(Eng.) Pitkanen, E. (Univ. Central Hosp., Unioninkatu 38, SF-00170 Helsinki 17, Finland). *Clin. Chim. Acta* 80(1):49-54; 1977.

The extent of D-threitol formation in the oral D-xylose tolerance test and the role of the liver in D-xylose metabolism were studied. An oral D-xylose tolerance test was carried out in 12 patients with portal liver cirrhosis, in 7 patients with active fatty liver disease, and in 29 subjects without liver diseases. D-xylose and D-threitol were measured by means of gas-liquid chromatography. Fifteen percent of the D-xylose dose excreted in urine within 5 hr was recovered as D-threitol. The proportion of D-threitol was greater when the collection was extended to 24 hr. The D-threitol excretion was markedly diminished in cirrhotic patients, suggesting that a substantial proportion of the D-xylose-D-threitol conversion occurs in the liver. No decrease was detected in patients with fatty liver disease. No significant change in D-xylose excretion was observed in liver cirrhosis or in fatty liver disease. D-threitol can be regarded as the main end product of D-xylose metabolism in man.

1492 DEMONSTRATION OF ANTIBODIES AGAINST ALBUMINS IN CHRONIC HEPATOPATHIES: THEIR RELATION TO ALBUMIN TURBIDITY AND SOME OTHER TESTS.

(Cze.) Fassati, P.; Jezkova, Z.; Spizek, J. (Oddeleni klinicke biochemie, OUNZ, Sokolovska 304, 190 00 Prague 9, Czechoslovakia). *Cas. Lek. Cesk.* 116(19):584-587; 1977.

Antibodies against albumins and their relation with albumin turbidity and other tests were studied in 50 patients with chronic hepatopathies (33 patients with liver cirrhosis or chronic hepatitis with clinical signs of developing cirrhosis [group 1], and 17 patients with hepatic steatosis [group 2]). Antibodies to albumins were found in 15 patients in group 1 (in 8/19 patients with medium degree of hepatic dysfunction and in 7/14 patients with severe dysfunction) and in 2 patients in group 2. Statistically significant positive correlation was found between the frequency of anti-albumin antibodies and the Takata reaction (correlation factor 0.402), the thymol turbidity test (correlation factor 0.411), and the gamma-globulin electrophoresis test (correlation factor 0.352) in group 1. The correlations between the anti-albumin antibodies and the albumin turbidity test and albumin and globulin electrophoresis tests were at the limit of statistical significance. The SGOT level correlated with the anti-albumin antibodies at the limit of statistical significance in group 2, but there were no other correlations.

1493 IMMUNE RESPONSE TO ϕX 174 IN MAN. 5. PRIMARY AND SECONDARY ANTIBODY PRODUCTION IN PRIMARY BILIARY CIRRHOSIS.

(Eng.) Thomas, H. C.; Holden, R.; Jones, J. V.; Peacock, D. B. (Western Infirmary, Glasgow, Scotland). *Gut* 17(11):844-848; 1976.

To study changes in the immune response induced by primary biliary cirrhosis (PBC), 12 patients with this disease were subjected to i.v. antigenic challenge with the bacteriophage ϕX 174, and the IgM and IgG components of the primary and secondary immune responses were measured. The patients were challenged with ϕX 174 (2.0×10^9 plaque-forming U) on day 0 and again between the 28th and 42nd day after the first challenge. The primary immune response to ϕX 174 in the PBC patients was within the normal range, the peak mean titer being 760 ± 308. However, the secondary response was significantly decreased ($p<0.01$). There was no correlation between the degree of depression of the peak response and the severity of the disease, as shown by the degree of cholestasis or hepatocellular necrosis. All patients showed a marked increase in the total serum IgM concentration, and a moderate increase in IgG. The ratio of serum IgM to IgG was above normal in all cases. During the secondary response there was a higher proportion of IgM antibody than in normal subjects. Sheep RBC (E) rosette forming cells were reduced in concentration in the PBC patients, but there was no correlation with either the clinical or histological grading of the disease. There was a positive correlation between the primary and secondary antibody titers and the thymus-derived (T) cell concentration in the peripheral blood ($r=0.73$, p 0.01; $r=0.84$, $p<0.001$). EAC rosette-forming cells were reduced in some patients, and there was a positive correlation between the concentration of these cells and the magnitude of both the primary ($r=0.66$, $p<0.05$) and secondary response ($r=0.89$, $p<0.001$). There was a poor correlation between phytohemagglutinin responsiveness and E rosetting cell concentrations. Depressed T cell function in PBC may be partially responsible for the proportionately lower IgG compared with IgM antibody response.

1494 HYPOXIA AND HYDROTHORACES IN A CASE OF LIVER CIRRHOSIS: CORRELATION OF PHYSIOLOGICAL, RADIOGRAPHIC, SCINTIGRAPHIC, AND PATHOLOGICAL FINDINGS.

(Eng.) Stanley, N. N.; Williams, A. J.; Dewar, C. A.; Blendis, L. M.; Reid, L. (Middlesex Hosp., Mortimer St., London W1N 8AA, England) *Thorax* 32(4):457-471; 1977.

The case of a 45-yr-old woman with liver cirrhosis complicated by cyanosis and recurrent right hydrothorax is described. A diagnostic pneumoperitoneum demonstrated that direct movement of ascites through a diaphragmatic defect was responsible for the hydrothoraces. Pulmonary function tests between episodes of hydrothorax showed severe arterial hypoxemia, a 23% right-to-left shunt, and a reduction in the carbon monoxide transfer factor to less than half the predicted value. Evidence of abnormal intrapulmonary arteriovenous communications was obtained by perfusion scanning. At necropsy the central tendon of the diaphragm showed numerous areas of thinning that were easily ruptured. Injection of the pulmonary arterial tree demonstrated precapillary arteriovenous anastomoses and pleural spider nevi. Morphometry provided quantitative evidence of pulmonary vasodilatation limited to the intra-acinar arteries, consistent with the effect of a circulating vasodilator. The scintigraphic and pathological findings suggested that shunting had been greater in the right than the left lung. Light microscopy of thin lung sections showed that the walls of small veins were thickened, and electron microscopy showed that this was due to a layer of collagen. The walls of capillaries were similarly thickened, which caused an approximately twofold increase in the minimum blood-gas distance and contributed to the reduction in transfer factor.

1495 EXERCISE-AGGRAVATED HYPOXEMIA AND ORTHODEOXIA IN CIRRHOSIS.

(Eng.) Kennedy, T. C.; Knudson, R. J. (Univ. Arizona Coll. Medicine, Tucson, AZ 85724). *Chest* 72(3):305-309; 1977.

The case of a patient with a syndrome characterized by hypoxemia aggravated by exercise, orthodeoxia, hypocapnia, and evidence of hyperdynamic circulatio complicating alcoholic cirrhosis is presented. The patient, a 63-yr-old man, first presented with dyspnea on exertion 4 yr after he had undergone a side-to-side portacaval anastomosis for bleeding esophageal varices. In addition to his other symptoms, there was hazy nodularity on chest x-ray films, clubbing, and reduced carbon monoxide diffusing capacity, but he had otherwise normal indices of pulmonary air flow, volume, and distribution of ventilation. The hypoxemia was more pronounced with the patient in the upright position an was further aggravated by exercise. This supports the presence of a shunt or shunt-like mechanism consisting of low-resistance vascular communication within the lung.

1496 TREATMENT OF REFRACTORY ASCITES BY REINFUSION OF THE ASCITIC FLUID.

(Ita.) Sturniolo, G. C.; Farini, R.; Martin, A.; Chiaramonte, M.; D'Angelo, A.; Ossi, E.; *et al.* (Cattedra Malattie Apparato Digerente, Istituto di Clinica medica I, Universita, Padova, Italy). *Recent. Prog. Med. (Roma)* 62(1):51-57; 1977.

Twenty-nine patients who developed ascites as a complication of cirrhosis were treated by reinfusion of concentrated ascitic fluid. Ascitic fluid was withdrawn from the abdominal cavity during peritoneal dialysis, concentrated by ultrafiltration, and reintroduced into the circulation through a vein in the arm. In the hour preceding introduction of the concentrated fluid, 1,000 ml of the unconcentrated ascitic fluid was recirculated through the body by a Watson Marlowe pump. Two hours after introduction of the concentrated fluid, patients were given 20-100 mg of furosemide i.v. Six hr after treatment began they were given a 3% solution of NaCl i.v. to compensate for the loss of electrolytes by ultrafiltration. Daily diuresis during the 5-day period preceding treatment and the 5-day period immediately after treatment showed a statistically significant increase of from 1.02 l to 1.5 l. There was no significant variation in azotemia, creatinemia, sodium or potassium levels, bilirubinemia or transaminase levels, and protein albumin or gamma globulin either before or after treatment. No major complications developed, although 48.8% of patients developed fever (not above 39 C), 53.3% developed chills, and 51% developed tachycardia (did not exceed 110 beats/min). Clinical improvement was observed for 2-27 months after treatment in 44% of the cases. Reinfusion of ascitic fluid is used for treatment of refractory cases and the majority of treated patients are in the final phases of the disease. It is difficult, therefore, to determine whether this treatment is effective solely in relieving symptoms or if it affects the ultimate course of the disease process.

1497 EFFECT OF β ADRENERGIC BLOCKING DRUGS IN THE RENIN-ALDOSTERONE SYSTEM, SODIUM EXCRETION, AND RENAL HEMODYNAMICS IN CIRRHOSIS WITH ASCITES. (Eng.) Wilkinson, S. P.; Bernardi, M.; Smith, I. K.; Jowett, T. P.; Slater, J. D. H.; Williams, R. (King's Coll. Hosp., Denmark Hill, London, SE5, England). *Gastroenterology* 73(4): 659-663; 1977.

The effects of propranolol and practolol on plasma renin activity were studied in 11 patients with cirrhosis and ascites. Their effects on the associated changes in aldosterone excretion, sodium excretion, and the intrarenal distribution of plasma flow were also investigated. As a result of effective β adrenergic blockade with either propranolol or practolol, plasma renin activity was suppressed in all 11 patients. In contrast, the effect on the rate of renal excretion of aldosterone was variable, suggesting that factors other than the renin-angiotensin system control the aldosterone secretion in cirrhosis. The changes in aldosterone could not be explained on the basis of changes in the plasma concentrations of potassium or sodium. The renal sodium excretion was inversely related to the values for aldosterone both before and after β adrenergic blockade, indicating a major role for aldosterone in regulating sodium excretion. A number of patients had an abnormal intrarenal distribution of plasma flow with a relative hypoperfusion of the renin-secreting outer cortical nephrons. Plasma renin activity was inversely related to outer cortical plasma flow, suggesting that the reduced outer cortical flow may be a stimulus to increased renin secretion. Because the abnormal intrarenal hemodynamic pattern was not corrected by suppression of plasma renin activity, and presumably angiotension II concentrations, it is unlikely that it is attributable to the known renal vasoconstrictor effects of angiotensin II.

1498 GROWTH HORMONE SECRETION AFTER L-DOPA TREATMENT OF LIVER CIRRHOSIS. (Ita.) Greco, A. V.; Ghirlanda, G.; Fedeli, G.; Rebuzzi, A.; Altomonte, L.; Manna, R. (Istituto di Patologia Medica, Universita Cattolica S. Cuore-Roma, Rome, Italy). *Minerva Med.* 67(47):3027-3032; 1976.

L-dopa (500 mg p.o.) was administered to 14 men with alcoholic cirrhosis of the liver and to 10 normal control subjects. L-dopa had no significant effect on plasma glucose or insulin levels in either the patients or controls. However, plasma levels of growth hormone (GH) were elevated in both groups. Ninety minutes after treatment, GH levels had risen from 1.97 ng/ml to 17.34 ng/ml in the controls and from 5.56 ng/ml to 28.03 ng/ml in the cirrhotics. These levels were significantly higher in the patients than in the controls. Three hours after treatment, GH levels returned to baseline values in both groups. This outcome was probably a reflection of the actual secretion of the hormone rather than its metabolism by the liver, since its rate of appearance and disappearance in the blood was the same in both the cirrhotics and controls.

1499 SURGICAL TREATMENT OF PORTAL HYPERTENSION BY MEANS OF SELECTIVE VASCULAR DERIVATIONS. (Spa.) Orozco, H.; Guevara, L.; Hernandez-Ortiz, J.; Elizondo, J.; Nieto, L.; Campuzano, M. (Natl. Inst. Nutrition, San Fernando Ave. and Tlalpan Viaduct, Mexico 22, D.F.). *Rev. Invest. Clin.* 29(2): 143-150; 1977.

Forty patients with portal hypertension were treated with selective venous shunts. Twenty patients had alcoholic cirrhosis, 16 had infectious cirrhosis, 1 had cirrhosis of unknown origin, and 3 had portal fibrosis. The 36 patients selected for the study who had elective operations were in a good state of general health otherwise, whereas the 4 patients who underwent emergency operation had profuse digestive hemorrhages and required immediate surgery. The surviving patients have been checked regularly every 3 months since the time of surgery. A selective end-to-end renosplenic shunt was performed in 24 patients (21 elective and 3 emergency operations); 9 patients had an elective distal splenorenal shunt (Warren), and 7 patients were treated by a selective end-to-side splenocaval shunt (4 elective without graft and 2 elective and 1 emergency with

Dacron grafts). Patient deaths within a month after surgery were considered as due to operative mortality. Mortality among the 36 patients who underwent elective surgery was 22%, and among the 4 who underwent emergency surgery it was 50%. Operative mortality for elective distal splenorenal shunt, selective end-to-end renosplenic shunt (elective), selective end-to-end renosplenic shunt (emergency), and selective end-to-side splenocaval shunt (elective) was 11.1%, 23%, 33%, and 33%, resp. The one patient who had emergency selective end-to-side splenocaval shunt died, bringing the total number of deaths to 10. Causes of death included infected ascites (1), liver failure (4), massive necrosis of the liver with reversal of portal venous blood flow (3), acute renal failure and hepatic failure (1), and acute cardiac, respiratory, and renal failure (1). Most frequent postoperative complications were upper gastrointestinal tract bleeding (7), hepatic insufficiency (24), and ascites (33). One patient had hepatic encephalopathy 2 yr after surgery. Survivors have no dietary restrictions, except for alcoholic beverages, and live normally.

1500 SURVIVAL IN PATIENTS WITH POSTNECROTIC CIRRHOSIS AND LAENNEC'S CIRRHOSIS UNDERGOING THERAPEUTIC PORTACAVAL SHUNT. (Eng.) Kanel, G. C.; Kaplan, M. M.; Zawacki, J. K.; Callow, A. D. (Univ. Chicago Hosp., 950 E. 59th St., Chicago, IL 60637). *Gastroenterology* 73(4, Part 1):679-683; 1977.

Survival rates were compared in 82 patients who underwent therapeutic portacaval shunt for Laennec's cirrhosis (45 cases), postnecrotic cirrhosis (29), or primary biliary cirrhosis (8). All patients were followed for at least 5 yr after shunt or until death. Survival rates were calculated by life-table methods. Eleven patients with postnecrotic cirrhosis had histological evidence of chronic active hepatitis. Survival rates were similar in alcoholic cirrhosis, postnecrotic cirrhosis, and primary biliary cirrhosis. Hepatic reserve provided the best criterion for predicting survival. The type of shunt, end-to-side, side-to-side, or splenorenal, did not influence survival. Histological evidence of chronic active hepatitis adversely affected survival in the patients with postnecrotic cirrhosis. However, histological evidence of ongoing alcoholic hepatitis in patients with Laennec's cirrhosis did not influence survival adversely. These data indicate that once a patient with cirrhosis has bled from esophageal varices, the etiology of the cirrhosis is not a major factor in determining survival after a therapeutic portacaval shunt.

1501 MESOCAVAL SHUNT IN PORTAL VEIN THROMBOSIS. (Ger.) Bergmann, H., Jr.; Brucke, P. (I. Chirurgische Abteilung, Allgemeines Krankenhaus der Stadt Linz, Krankenhausstrasse 9, A-4020 Linz, Austria). *Wien. Med. Wochenschr.* 127(12):364-368; 1977.

Two cases of mesocaval shunt operation in portal vein thrombosis are reported. Emergency mesocaval shunt operation was performed in a 48-yr-old man with portal hypertension and portal vein thrombosis who had undergone total gastrectomy. Mesocaval shunt was necessary for portal decompression due to massive parenchymal hemorrhage during splenectomy. Mesocaval shunt was performed routinely in a 10-yr-old boy with portal vein thrombosis and umbilical sepsis. The surgery was successful in both cases. Mesocaval shunt is indicated in portal vein thrombosis with ascites and esophageal varices and in children in whom splenorenal shunt is impossible due to the small diameter of the splenic and renal veins. It is also useful in all cases where splenorenal shunt is anatomically impossible, e.g., prehepatic block after extirpation of the spleen, thrombosed splenorenal shunt, intrahepatic block with cicatrization, and shrinkage or inflammation of the hepatoduodenal ligament.

1502 TRANSDUODENOPANCREATIC INTERPOSITION MESOCAVAL SHUNT USING AN INTERNAL JUGULAR VEIN AUTOGRAFT. (Eng.) Moreno Gonzalez, E.; Hebrero San Martin, J.; Solis Herruzo, J. A.; Rico Selas, P.; Rodriguez Agullo, J. L. (Digestive Surgery Dept., Ciudad Sanitaria de la Seguridad Social, Madrid, Spain). *Surg. Gynecol. Obstet.* 145(4): 565-569; 1977.

The use of transduodenopancreatic interposition mesocaval shunt using an internal jugular vein autograft is reported in 26 patients with bleeding esophageal varices, and the modification of this procedure in 4 patients with superior mesenteric vein anatomic abnormalities is described. These abnormalities made the usual subduodenal position of the jugular vein graft impossible. In these patients, a small pancreatectomy was performed between the transverse portion of the duodenum and the right aspect of the superior mesenteric vein, placing the interposition mesocaval shunt in a transduodenopancreatic position. No patient has had any bleeding after the operation, nor have esophageal varices been found at the time of the last examination (24 months after surgery). During this period, all patients showed a remarkable tolerance to proteins, and no patient has been on a low protein diet.

1503 HISTOCHEMICAL ACTIVITY OF γ-GLUTAMYLTRANSPEPTIDASE IN NORMAL AND CHOLESTATIC LIVER: AN INVERSE CORRELATION WITH INTRAHEPATIC ACCUMULATION OF BILE SALTS [Abstract]? (Eng.) Busachi, C. A.; Mebis, J.; Desmet, V. J. (Departement Medische Navorsing, Academisch Ziekenhuis Sint Rafael, Leuven, Belgium). *Digestion* 16(4):341; 1977.

1504 INCREASED TRANSCAPILLARY ESCAPE RATE OF ALBUMIN IN CIRRHOSIS AND ITS RELATION TO ASCITES FORMATION [Abstract]. (Eng.) Henriksen, J. H.; Parving, H. H.; Ranek, L.; Winkler, K.; Lassen, N. A. (Hvidovre Hosp., Copenhagen, Denmark). *Digestion* 16(4):347; 1977.

1505 FACTORS INFLUENCING ASCITES REABSORPTION. RELATIONSHIP TO DIURETIC-INDUCED AZOTAEMIA [Abstract]. (Eng.) Bosch, J.; Arroyo, V.; Sanz, G.; Estrada, L.; Rodes, J. (Hospital Clinico y Provincial, Barcelona, Spain). *Digestion* 16(4): 327; 1977.

1506 PARENTERAL 1,25-DIHYDROXYCHOLECALCIFEROL IN HEPATIC OSTEOMALACIA [Abstract]. (Eng.) Long, R. G.; Varghese, Z.; Meinhars, E.; Skinner, R. K.; Wills, M. R.; Sherlock, S. (Royal Free Hosp., London, England). *Digestion* 16(4):326; 1977.

1507 RENIN SECRETION RATE AND HEPATIC METABOLISM OF RENIN AND ALDOSTERONE IN CIRRHOSIS OF THE LIVER [Abstract]. (Eng.) Bosch, J.; Arroyo, V.; Mauri, M.; Rivera, F.; Navarro, F.; Rodes, J. (Hospital Clinico y Provincial, Barcelona, Spain). *Digestion* 16(4):349-350; 1977.

1508 ENZYME INDUCTION IN CIRRHOTIC PATIENTS DURING SPIRONOLACTONE THERAPY [Abstract]. (Eng.) Miguet, J. P.; Thebaut, A.; Dhumeaux, D. (Hopital Henri Mondor, Creteil, France). *Digestion* 16(4):353-354; 1977.

1509 USE OF β-ADRENERGIC BLOCKADE IN DIURETIC-INDUCED RENAL IMPAIRMENT IN CIRRHOSIS WITH ASCITES [Abstract]. (Eng.) Wilkinson, S. P.; Bernardi, M.; Wheeler, P. G.; Smith, I. K.; Williams, R. (King's Coll. Hosp., Medical Sch., London, England). *Digestion* 16(4):351; 1977.

LIVER AND BILIARY TRACT

Gallbladder and Biliary Tract Diseases

1528 GALLBLADDER DISEASE--II. UTILIZATION OF THE LIFE TABLE METHOD IN OBTAINING CLINICALLY USEFUL INFORMATION: A STUDY OF 62,739 WEIGHT-CONSCIOUS WOMEN. (Eng.) Bernstein, R. A.; Giefer, E. E.; Vieira, J. J.; Werner, L. H.; Rimm, A. A. (Medical Coll. Wisconsin, 1725 W. Wisconsin Ave., Milwaukee, WI 53233). *J. Chronic Dis.* 30(8):529-541; 1977.

In a cross-sectional study of 62,739 women who were members of a club concerned with weight control problems, cohorts were reconstructed in a study to determine incidence rates and relative risks of gallbladder disease (GBD). The life-table technique was used to compare age-specific subgroups of the population by obesity levels and parity. This cohort analysis allowed the calculation of incidence rates which were used to evaluate risk factors of GBD. Relative risk and probability of GBD were also determined, and their application to a hypothetical patient was demonstrated. The probability of GBD significantly increased with increasing weight, age, and parity, in that order of importance. A multiple regression analysis revealed that obesity accounted for a large portion of the variation of GBD. About 88% of the variation was explained by the linear combinations of obesity, age, and parity. The risk of GBD among extremely obese women in their 20's was greater than six times that of women with normal weight in their 20's. For the entire population under study, the probability of developing GBD by age 60 was estimated to be 32.9/100 women.

1529 ACUTE CHOLECYSTITIS: 137 PATIENTS STUDIED BY INFUSION TOMOGRAPHY OF THE GALLBLADDER. (Eng.) Moncada, R.; Cardoso, M.; Danley, R.; Rodriguez, J.; Kimura, K.; Pickleman, J.; *et al.* (Loyola Univ. Medical Center, Maywood, IL 60153). *Am. J. Roentgenol.* 129(4):583-585; 1977.

Clinical experience with inflammatory cholecystopathy recognized in 137 patients studied by gallbladder infusion tomography is presented. The diagnostic accuracy of acute cholecystitis in 70 patients in whom this condition was suspected was 96% in positive and 94% in negative histologically proven cases. Infusion tomography of the gallbladder is an accurate, rapid, and safe diagnostic aid in the evaluation of acute cholecystitis. In cases of chronic cholecystitis, infusion tomography may be confirmatory but should not be relied on as a final diagnostic test due to a high percentage of false negative cases; only 64% of 18 cases of histologically proven chronic cholecystitis were diagnosed by this method.

1530 ENDOSCOPIC RETROGRADE CHOLANGIOPANCREATOGRAPHY (ERCP) PERFORMED IN CHILDREN. (Eng.) Urakami, Y.; Seki, H.; Kishi, S. (Sch. Medicine, Tokushima Univ., Kuramotocho, Tokushima City, 770, Japan). *Endoscopy* 9(2):86-91; 1977.

Endoscopic retrograde cholangiopancreatography (ERCP) was performed in three children to establish its diagnostic value in young patients. A normal duodenofiberscope (JF-B2) was used with two patients (a 6-yr-old boy and 8-yr-old girl with colic abdominal pains) under general anesthesia and with a 13-yr-old boy (presenting with epigastric pain and abdominal discomfort) after premedication (1 ml Buscopan, i.m., and local anesthesia with xylocain spray). The technique of examination was the same as in adults. ERCP confirmed dilatation of the left hepatic and common bile ducts in the 6-yr-old boy and a cystic stricture of the extrahepatic bile duct and dilatation of the intrahepatic biliary tree in the 8-yr-old girl. ERCP also showed that the distal common bile duct was narrowed in both patients (extirpation of the cyst and hepatojejunostomy were performed). ERCP revealed numerous areas of narrowing and dilatation diffusely scattered throughout the pancreatic duct of the 13-yr-old boy. The common bile duct was partially visualized. Operation and autopsy disclosed a tumorous lesion involving the duct system (Burkitt's lymphoma). ERCP is recommended in every suspected case of choledochal cyst because it is superior to all other procedures in clarifying exactly the extention of the dilatation, the state of the distal common bile duct, and the relation between biliary and pancreatic duct systems; therefore an exact preoperative diagnosis can be made. Improvements in the duodenofiberscope for children may open the new field of ERCP also in newborns for the diagnosis and differentiation of congenital atresia of the common bile duct.

1531 PERCUTANEOUS CHOLANGIOGRAPHY WITH THE OKUDA NEEDLE. (Eng.) Hinde, G. De B.; Smith, P. M.; Craven, J. L. (Llandough Hosp., Nr. Penarth, South Glamorgan, Wales). *Gut* 18(8):610-614; 1977.

The results of percutaneous cholangiography with the Okuda needle in 42 consecutive patients with a clinical diagnosis of obstructive jaundice are presented. The steel needle used was smaller in diameter than the original Okuda needle (0.5 mm, 25 gauge versus 0.7 mm, 27 gauge). An aimed anatomical approach was made from the right flank to the area above the junction of the right and left hepatic ducts; this approach was achieved with the help of two lead markers. Six patients had intrahepatic cholestasis. The technique demonstrated the biliary anatomy in 41 patients, and the radiological diagnosis was confirmed by laparotomy, necropsy, or liver biopsy. There were no significant complications. Laparotomy, when indicated, was performed earlier in the course of the jaundice, and it was avoided in seven patients. Precise knowledge of the site of the obstruction was of great help to the surgeon. This technique represents an important advance in the management of the jaundiced patient. The rarity of complications is attributed to prophylactic antibiotics, the slimness and flexibility of the needle, and the lateral entry point, which provides protection against bile leakage through the thickness of the liver.

1532 PLASMA DISAPPEARANCE AND CONJUGATION OF [^{14}C]CHOLIC ACID IN PATIENTS WITH OBSTRUCTIVE JAUNDICE. (Eng.) Horak, W.; Knoflach, P.; Schuster, E.; Kemmenesi, W.; Grabner, G. *In: Bile Acid Metabolism in Health and Disease. Proceedings of the IV Bile Acid Meeting held at the Hilton Hotel, Basel, Switzerland, October 11-12, 1976.* University Park Press. (Baltimore, MD): 247-251; 1977.

To investigate what mechanism (i.e., impaired uptake, conjugation, or excretion) is involved in the pathogenesis of impaired bile acid clearance in patients with obstructive jaundice, plasma disappearance and conjugation of i.v.-injected free [^{14}C]-cholic acid were investigated in five healthy subjects and in seven patients with obstructive jaundice. Radioactivity was measured in plasma samples and in the individual plasma bile acid fractions after separation by thin-layer chromatography. Plasma curves of free, conjugated, and total [^{14}C]radioactivity were calculated by an iterative nonlinear least-squares fitting procedure using a computer. A compartment model was applied to estimate the transfer rates of [^{14}C]cholic acid between free and conjugated plasma, liver, and bile compartments. In the patients, the disappearance of total plasma radioactivity was greatly prolonged, while the plasma disappearance of free [^{14}C]cholic acid was nearly normal. The impaired disappearance of total plasma radioactivity could be attributed to a slight decrease of hepatic uptake and to a considerable reflux of conjugated [^{14}C]cholate from liver to plasma. While the conjugation rate was similar to healthy subjects, the biliary excretion rate was practically null in obstructive jaundice. Free [^{14}C]cholic acid plasma clearance may allow an estimation of hepatic bile acid uptake and conjugation independently from disorders of biliary excretion, while large amounts of conjugated [^{14}C]cholate appearing in plasma indicate cholestasis. This test therefore may provide new information for the differential diagnosis of the patient with jaundice.

1533 COMPOSITION OF BILE IN POPULATIONS AT ELEVATED RISK OF CHOLELITHIASIS. (Ita.) Ponz de Leon, M.; Ferenderes, R.; Carulli, N. (Istituto di Clinica Medica Generale e Terapia Medica della Universita, Modena, Italy). *Minerva Med.* 67 (53):3483-3490; 1976.

The cause of cholelithiasis in diabetics and cirrhotics was sought by studying the composition of bile in 14 controlled diabetics, 10 cirrhotics, 15 cholelithiasis patients, and 8 controls. Samples were taken after a fast of at least 12 hr using a double radiopaque catheter so that separate samples of gastric and duodenal juices could be obtained. Study of bile acids, phospholipids, and cholesterol showed a significantly elevated index of saturation in diabetics compared to controls ($p<0.0025$), with a lesser but still significant elevation in cholelithiasis patients ($p<0.01$) and no significant elevation in cirrhosis patients. Elevation of the index was related to a decrease in the level of bile acids and an increase in the level of cholesterol. In terms of total composition (expressed in percent), cholesterol in controls was 5.6 ±

2.0 compared to 9.5 ± 2.5 in diabetics (p=0.005), but 7.5 in cholelithiasis (not significant). In the diabetics and cirrhotics, phospholipids were increased in comparison to controls (18.5 ± 8.3 and 12.7 ± 7.0 versus 16.4 ± 7.9%), but not to a significant level. Bile acids in diabetics, cholelithiasis patients, and cirrhotics were decreased compared to controls, but again not to a significant degree. Thus, there are clear physiopathological changes in bile composition in diabetics to explain the occurrence of cholelithiasis, but no cause for cholelithiasis in cirrhotics was elucidated by these studies.

1534 CHANGES IN BILE LIPIDS ACCOMPANYING OOPHORECTOMY IN A PREMENOPAUSAL WOMAN. (Eng.) Bennion, L. J. (Natl. Inst. Health, 4212 N. 16th St., Phoenix, AZ 85016). *N. Engl. J. Med.* 297(13):709-711; 1977.

Changes in bile lipids were examined in a premenopausal woman (36 yr old) who underwent bilateral oophorectomy. Oophorectomy was carried out because of adenocarcinoma of the endometrium. Bile acid pool size, bile acid composition, and gallbladder bile lipid composition were studied 2 months before and again 3 months after surgery. Whereas there was no substantial change in the relative proportions of bile acids, the size of the total bile acid pool increased from 1,040 mg before to 2,170 mg after the operation. The gallbladder bile cholesterol concentration was decreased after oophorectomy (4.8 after versus 7.0 M% before). Cholesterol saturation was 100% before and 81% after surgery, according to one method and 70% before and 49% after, according to a second method. This change suggests that endogenous ovarian hormones may influence the propensity to gallstone formation in a manner similar to that of exogenous estrogens and progestins.

1535 EFFECT OF PROLONGED FEEDING WITH CHENODEOXYCHOLIC ACID ON BILE IN PATIENTS WITH AND WITHOUT GALLSTONES. (Eng.) Bateson, M. C.; Ross, P. E.; Murison, J.; Bouchier, I. A. D. (Ninewells Hosp. and Medical Sch., Dundee, Scotland). *Gut* 18(8):599-605; 1977.

The effect of prolonged chenodeoxycholic acid therapy on bile cholesterol saturation was studied. Nineteen patients who received chenodeoxycholic acid (750 mg/day) for 6 months had duodenal bile aspirated before and after treatment. In five patients with hypertriglyceridemia but no gallstones, cholesterol saturation was reversed in every case, the mean cholesterol saturation index (SI) changing from 1.38 ± 0.31 to 0.68 ± 0.06 ($p<0.005$). In 14 patients with gallstones, there was also an improvement in bile cholesterol content, but this change was not sufficient to produce mean unsaturation, the SI changing from 1.55 ± 0.52 to 1.13 ± 0.43 ($p<0.05$). Only 7 of 14 patients with gallstones achieved cholesterol unsaturation. In four patients with hypertriglyceridemia and gallstones, mean unsaturation was produced and the SI changed from 1.70 ± 0.45 to 0.86 ± 0.47 ($p<0.05$). When all nine patients with hypertriglyceridemia were grouped, the mean fell from 1.52 ± 0.40 to 0.76 ± 0.30 after therapy ($p<0.001$). In contrast, the 10 patients without hypertriglyceridemia showed no significant fall in SI, which was 1.50 ± 0.54 before and 1.24 ± 0.40 after therapy. The ability of chenodeoxycholic acid feeding to improve bile saturation with cholesterol correlated with the presence of hypertriglyceridemia whether or not gallstones were present. It did not correlate with gallstone dissolution or body weight.

1536 CHANGES OF BILIARY BILE ACIDS IN PATIENTS AFTER ADMINISTRATION OF URSODEOXYCHOLIC ACID. (Eng.) Makino, I.; Nakagawa, S. *In: Bile Acid Metabolism in Health and Disease. Proceedings of the IV Bile Acid Meeting held at the Hilton Hotel, Basel, Switzerland, October 11-12, 1976.* University Park Press (Baltimore, MD): 211-217; 1977.

The value of ursodeoxycholic acid (UDCA) for gallstone dissolution was studied in 44 patients with radiolucent gallsones. The patients were randomly allocated to one of three treatment regimens: placebo (lactose) or 150 or 600 mg/day of UDCA for 6 months. No patient in the placebo group responded. Unequivocal dissolution of gallstones was observed in 8 of 31 patients receiving UDCA; 38% of the patients receiving the lower dose and 13% of those receiving the higher dose responded. UDCA possessed neither apparent hepatotoxicity nor cathartic activity. Desaturation of biliary cholesterol was induced by UDCA administration, and UDCA in bile increased in proportion to dose of UDCA. The major fecal bile acid of patients receiving UDCA was lithocholate. Serum bile acid levels rose slightly after UDCA treatment (2.4 ± 1.7 µg/ml), and UDCA occupied over 50% of total bile acid. These results confirm the efficacy of UDCA for gallstone dissolution.

1537 STRUCTURAL ALTERATIONS OF THE LIVER IN CHOLELITHIASIS. (Ita.) Marenco, G.; Menardo, G.; Gazzaniga, G. M.; Conti, U. (Istituti Ospedalieri Santa Corona, Pietra Ligure, Italy). *Pathologica* 69(987/988):77-85; 1977.

Structural alterations in the liver were studied in 85 patients with calculi of the gallbladder (60 patients) or of both the gallbladder and the common bile duct (20 patients). Of the 60 patients with calculi of the gallbladder 20 were asymptomatic. Each patient had surgical biopsy of the liver at some distance from the cholelithiasis. Bile duct calculi cause inflammatory infiltration into the portal spaces, proliferation of the bile ducts at the margin of the portal spaces, inflammatory infiltration into the interlobular spaces, and biliary hardening. Gallbladder were characterized by chronic inflammation and fibrotic lesions of the portal spaces. Structural alterations of the liver were most pronounced in patients with a clinical history of frequent attacks of colic. These structural alterations occurred in about 85% of the cases and were different than the morphologic pattern of chronic aggressive hepatitis.

1538 MORTALITY OF OPERATIONS ON GALLBLADDER AND BILE DUCTS PERFORMED IN A TRAINING HOSPITAL.

(Eng.) Schothorst, A. (Dept. Surgery, St. Geertruiden Gast- of Ziekenhuis, Deventer, Netherlands). *Arch. Chir. Neerl.* 29(2):109-116; 1977.

A retrospective study was made of the mortality rate from 990 operations done during a 6-yr period (1967-1972) at the St. Geertruiden Gasthuis of Ziekenhuis to determine whether surgery in a training hospital adversely affected the mortality rate. Five groups of operations were studied: 1) cholecystectomy (397, of which 234 operations were by surgeon), 2) cholecystostomy (5), 3) cholecystectomy plus choledochotomy (504, of which 281 operations were by surgeon), 4) re-exploration or inspection of the biliary tract (44, all by a surgeon), and 5) operations necessitated by malignant neoplasia in the region of the gallbladder or bile ducts and pancreas (40, all by a surgeon). Zero percent surgical mortality was shown in assistant-operated patients, suggesting a low risk factor for patients with biliary tract pathology; the low mortality was attributed to preoperative selection of patients to be operated on by assistants or by surgeons. A higher incidence of complications and mortality is suggested in the group over 70 yr of age, but age was no criterion in determining whether an operation was to be done by an assistant. It is concluded that the training system does not work to the patient's disadvantage.

1539 ULTRASONIC SCANNING IN POSTCHOLECYSTECTOMY CHOLEDOCHOLITHIASIS.

(Eng.) Sapala, M. A.; Steel, W. B.; Resto Soto, A. D.; Sapala, J. A. (Hutzel Hosp. and Wayne State Univ. Sch. Medicine, 4707 St. Antoine, Detroit, MI 48201). *Surgery* 84(4):420-424; 1977.

Four patients underwent ultrasonic scanning of the right upper quadrant for the evaluation of unexplained jaundice and fever. Each patient had undergone a previous cholecystectomy with common bile duct exploration for biliary tract calculi. No patient at that time revealed retained stones on either intraoperative or postoperative cholangiograms. In none of the patients studied was the exact nature of the obstruction appreciated by the clinical and laboratory data. All patients revealed biliary duct dilatation on ultrasound, and the majority demonstrated a bile duct calculus as well. The authors do not recommend that ultrasonic scanning be substituted for p.o. or i.v. cholangiography when the latter can be performed. Nor should ultrasonic scanning be used to replace endoscopic retrograde cholangiopancreatography, percutaneous transhepatic cholangiography, or even liver biopsy if these procedures are indicated and can be completed with a reasonable degree of safety. However, ultrasound can be very helpful in the occasional patient whose biliary tract obstruction defies exact diagnosis when routine dye studies and invasive diagnostic procedures are neither accurate nor feasible.

1540 TRANSAMPULLARY SEPTECTOMY FOR POST-CHOLECYSTECTOMY PAIN.

(Eng.) Moody, F. G.; Berenson, M. M.; McCloskey, D. (Univ. Utah Coll. Medicine, Salt Lake City, UT 84132). *Ann. Surg.* 186(4):415-423; 1977.

A systematic prospective study of transampullary septectomy combined with sphincteroplasty was carried out in patients with severe, long-standing postcholecystectomy pain. Twenty-eight patients had excision of the common wall between the terminal bile duct and duct of Wirsung (ampullary septum). Twenty-two also had a sphincteroplasty; six had had this procedure previously. Pancreatic function studies, scintiscans, ultrasound, and pancreatograms were nondiagnostic. Hyperamylasemia was an uncommon finding. Eight patients had evidence of mild pancreatitis at exploration. There was gross scarring of the ampullary septum in 22 cases. Histologic examination revealed inflammation in 12 septa; the degree of fibrosis could not be assessed, since 14 control septa from autopsy material free from biliary tract disease revealed a comparable degree of collagen and smooth muscle. There were no deaths, and minimal morbidity. In follow-up from 7 to 59 months (mean=26), 16 patients are relatively free of pain, 5 have occasional episodes that require non-narcotic analgesics, and 7 have gained no relief from the operative procedure. A randomized controlled trial is recommended.

1541 INFANTILE HEPATITIS AND CONGENITAL ATRESIA OF BILE DUCTS.

(Eng.) Watanabe, W.; Kobayashi, O. (Niigata Univ. Sch. Medicine, Niigata, Japan). *Acta Med. Biol.* 23(3/4):191-213; 1976.

Etiological, clinical, and histological data on 67 infants with infantile hepatitis and 41 infants with congenital biliary atresia observed from 1961 to 1974 are reported. Comparison of prenatal histories showed that the infants with hepatitis had shorter average gestation, lower birth weights, and familial incidence of disease. Association of other congenital anomalies such as Down's syndrome, microcephalus, and cerebral palsy were observed with Tests for Australia antigen were positive in 1/20 infants with hepatitis tested and negative in all 7 infants with biliary atresia tested. Histological examination of biopsy specimens can readily distinguish between the two diseases in the early stages. Ductal proliferation appears to be the most reliable sign of biliary malformation. The severe cases of infantile hepatitis are difficult to distinguish from biliary atresia. Electron microscopy was the method of choice for differentiating between the two syndromes. Infantile hepatitis and congenital atresia of the bile ducts may be analogous diseases caused by viral infections or noxious agents during the first trimester of pregnancy.

1542 "CYSTS" OF THE COMMON BILE DUCT (DYSPLASIA OF THE COMMON BILE DUCT). (Ita.) Pezzi, A.; Jasonni, V.; Brusori, G. (Policlinico S. Orsola, Bologna, Italy). *Minerva Med.* 67(7):443-450; 1976.

A review of the salient features of cholecystic dysplasia is given. Extrahepatic cholecystic dysplasia is classified into choledochal cysts, choledochal diverticuli, and choledoceles. Choledochal diverticuli cause torsion and strangulation and often result in stenosis, which extends to the superior margin of the pancreas. Choledoceles cause the ampulla of Vater to protrude into the duodenum; there is also some slight tumifaction at the extreme distal end of the biliary-pancreatic path. Congenital ectasia is a severe form of cholecystic dysplasia that causes extensive involvement of the liver and that may result in renal failure. Cases with systemic and intra- and extrahepatic involvement are classified as type IV cholecystic dysplasia and are characterized by involvement of the primary bile duct.

1543 APLASIA OF THE GALLBLADDER WITH COMMON DUCT STONES. (Eng.) Wahlby, L. (Univ. Hosp. Umea, Umea, Sweden). *Acta Chir. Scand.* 143(4):241-243; 1977.

The case of a 79-yr-old woman with gallbladder aplasia and common duct stones is reported. The patient presented with right upper quadrant tenderness and a 2-week history of jaundice. She did not respond to conservative treatment, and the serum bilirubin level increased to 205 μM. A preoperative cholangiography revealed no gallbladder or cystic duct. At laparotomy, the liver was enlarged, icteric, and slightly fibrotic. No gallbladder or cystic duct was present. The common duct was 25 mm wide and contained four faceted stones. The patient remains asymptomatic 4 yr after choledocholithotomy and drainage. Only 22 cases of aplasia of the gallbladder with commmon duct stones have previously been reported.

1544 CARCINOMA OF THE EXTRAHEPATIC BILIARY TRACT: STUDY OF 62 CASES AND REPORT OF THE BRAZILIAN LITERATURE (PART III). (Por.) Filho, P. S. (No affiliation given). *Rev. Bras. Med.* 33(3):104-110; 1976.

1545 ENDOSCOPIC RETROGRADE CHOLANGIOPANCREATOGRAPHY. (Pol.) Karcz, D.; Legutko, J.; Popiela, T. (Acad. Medicine, Cracow, Poland). *Pol. Tyg. Lek.* 32(14):513-516; 1977.

1546 CONSIDERATIONS ON BILIARY ILEUS. (Ita.) Abrescia, F.; Pederzoli, P.; Tenchini, P.; Modena, S. (Istituto di Chirurgia Generale, Universita di Padova, Padova, Italy). *Chir. Ital.* 28(1):63-75; 1976.

1547 RADIOLOGY OF ACALCULOUS GALL BLADDER DISEASE: A NEW SIGN. (Eng.) Russell, J. G. B.; Keddie, N. C.; Gough, A. L.; Galland, R. B. (Royal Infirmary, Manchester, England). *Br. J. Radiol.* 49(581):420-424; 1976.

1548 BACTERIOLOGICAL INVESTIGATIONS OF BILE FOLLOWING OPERATIONS FOR VARIOUS CONDITIONS. (Ita.) Sianesi, M.; Berri, T. (Istituto di Clinica Chirurgica Generale, Universita degli Studi di Parma, Parma, Italy). *Chir. Ital.* 28(4):341-355; 1976.

1549 COMMON BILE DUCT IN ACUTE CHOLECYSTITIS: REPORT OF 116 CASES. (Ita.) Dell'Anna, B.; Sianesi, M.; Paroni, R. (Istituto di Patologia Speciale Chirurgica, Universita degli Studi di Parma, Parma, Italy). *Chir. Ital.* 28(1):39-62; 1976.

1550 ANATOMO-SURGICAL ASPECTS OF PEROPERATIVE CHOLANGIOGRAPHY IN BILIARY LITHIASIS. (Ita.) Bianca, T.; Fusto, A.; Donati, A.; Morici, V. (Istituto di Anatomia Chirurgica dell'Universita di Catania, Catania, Italy). *Chir. Ital.* 28(1):18-38; 1976.

1551 OBSERVATIONS ON THE IMMEDIATE AND LONG-TERM RESULTS OF 112 OPERATIONS OF INTERNAL BILIARY DRAINAGE. (Ita.) Battistini, C.; Sianesi, M.; Farinon, A. M.; Dell'Anna, B. (Istituto di Patologia Speciale Chirurgica, Universita degli Studi di Parma, Parma, Italy). *Chir. Ital.* 28(1):1-17; 1976.

GENERAL

1619 RELATIVE IMPORTANCE OF VIRUSES AND BACTERIA IN THE ETIOLOGY OF PEDIATRIC DIARRHEA IN TAIWAN. (Eng.) Echeverria, P.; Ho, M. T.; Blacklow, N. R.; Quinnan, G.; Portnoy, B.; Olson, J. G.; Conklin, R.; *et al.* (Harvard Medical Sch., 25 Shattuck St., Boston, MA 02115). *J. Infect. Dis.* 136(3):383-390; 1977.

Eighty Taiwanese children with diarrhea were studied to determine the relative importance of (a) reovirus-like agent (RVLA), (b) *Escherichia coli* that produce heat-stable and heat-labile toxin, (c) invasive *E. coli*, (d) *Salmonella*, *Shigella*, and *Vibrio*, (e) enteroviruses, and (f) parasites in the etiology of pediatric diarrhea. Of 75 patients tested for evidence of infection with RVLA by electron microscopy of stools and/or by assays of complement-fixing and immunofluorescent antibody response to the serologically related Nebraska calf diarrhea virus, 42 were positive. Of children whose stools contained the agent, 90% showed a fourfold or greater rise in titer of immunofluorescent antibodies, and 85% developed a fourfold or greater rise in titer of complement-fixing antibodies to the agent. Strains of *E. coli* producing only heat-labile toxin (LT) were isolated from 7% of 57 ill children who had not received previous antibiotics and from 4% of 131 healthy control children (p=0.49). Strains of *E. coli* producing only heat-stable toxin (ST) were isolated from 5 of 57 age-matched children in the 131 healthy controls tested. Invasive *E. coli* were not found. In addition, three of six children with bacterial and/or serological evidence of an infection with LT-producing *E. coli* and four of five children infected with ST-producing *E. coli* had infections with RVLA. RVLA appeared to be the major cause of diarrheal illness in Taiwan during the summer of 1975, whereas toxigenic *E. coli* appeared to be responsible for a smaller proportion of pediatric enteritis.

1620 SYMPTOMATIC TREATMENT OF DIARRHEA WITH BISMUTH SUBSALICYLATE AMONG STUDENTS ATTENDING A MEXICAN UNIVERSITY. (Eng.) DuPont, H. L.; Sullivan, P.; Pickering, L. K.; Haynes, G.; Ackerman, P. B. (6400 West Cullen St., Houston, TX 77030). *Gastroenterology* 73(4, Part 1):715-718; 1977.

The value of bismuth subsalicylate in the symptomatic treatment of diarrhea was studied in students attending a Mexican university who developed diarrhea. One hundred eleven students were given 30 ml each half hour until eight doses (total dose of active drug, 4.2 g) were given, and 58 students received twice this dose (8.2 g of active drug) over the 3.5-hr treatment period. The number of unformed stools was significantly decreased in both bismuth subsalicylate treatment groups compared to the placebo controls for the period 4 to 24 hr after therapy. A reduction in diarrhea was additionally noted for the duration of the 48-hr surveillance period for the students receiving the higher dose of active drug. Subjective relief within 24 hr of therapy of the symptoms of diarrhea, nausea, and abdominal pain or cramps was reported with a significantly increased frequency in the bismuth subsalicylate group. The most pronounced effect of the treatment occurred in the United States students with diarrhea who had recently arrived in Mexico. This appeared to be related to the favorable effect of bismuth subsalicylate on the course of toxigenic *Escherichia coli* infection. The thirty-two students with shigellosis did not experience a prolonged illness in either treatment group. Bismuth subsalicylate is effective in reducing diarrhea, regardless of etiology.

1621 THORACIC SPINAL CORD TUMOR PRESENTING WITH DYSAUTONOMIC DIARRHEA. (Eng.) Fricke, R. D.; Romine, J. S. (Veterans Admin. Section, 3350 La Jolla Village Drive, San Diego, CA 92161). *Gastroenterology* 73(5):1152-1156; 1977.

The case of a 52-yr-old man with an ependymoma who presented with dysautonomic diarrhea is described. The patient had incapacitating diarrhea of 1-month duration and developed orthostatic hypotension and progressive long tract central nervous system signs. No enteric disease was found to account for the diarrhea. An intramedullary midthoracic spinal cord tumor was found. Diarrhea and hypotension resolved after local cord decompression and irradiation of the tumor. Dysmotility caused by interruption of thoracic sympathetic pathways to the gut was considered responsible for the diarrhea, and altered splanchnic hemodynamics for the hypotension. The regional autonomic neuroanatomy and the known effects of the autonomic nervous system upon bowel function and the splanchnic circulation explain the patient's symptoms.

1622 MASSIVE RECURRENT HEMORRHAGE OF THE DISTAL PART OF THE DIGESTIVE TRACT DUE TO HEREDITARY HEMORRHAGIC TELANGIECTASIA (OSLER'S SYNDROME). (Fre.) Besson, A.; Saegesser, F. (Service de Chirurgie A, CHUV, CH-1011 Lausanne, Switzerland). *Schweiz. Med. Wochenschr.* 107(30):1057-1064; 1977.

Hereditary hemorrhagic telangiectasia was diagnosed in a 67-yr-old woman with multiple angiomas of the head, trunk, and fingers by emergency selective angiography of the celiac trunk and superior and inferior mesenteric arteries during uncontrollable rectal hemorrhage. The investigations revealed a large arteriovenous fistula in the cecal region, originating from a large ruptured telangiectasia. Right hemicolectomy with anastomosis between the ileum and ascending colon under angiographic control of the resected specimen was successful; the patient was in good condition more than 1 yr after surgery. The patient's brother has the same disease, and their mother had frequent epistaxis, a typical sign of telangiectasia.

1623 REGULATION OF POOL SIZE OF BILE ACIDS IN MAN. (Eng.) Mok, H. Y. I.; von Bergmann, K.; Grundy, S. M. (Veterans Admin. Hosp., 3350 La Jolla Village Drive, San Diego, CA 92161). *Gastroenterology* 73(4, Part 1):684-690; 1977.

Various components of the enterohepatic circulation were investigated in 33 subjects to determine their effects on bile acid pool size. Seven patients had increases in plasma cholesterol with near normal triglycerides, and six others had raised plasma triglycerides. The pool size and secretion rates of bile acids were measured using an intestinal perfusion method, and bile acid synthesis was determined by fecal excretion. From these measurements, cycling frequency of the pool and intestinal absorption of bile acids were calculated. The results were analyzed for the group as a whole and for four subgroups based on incremental pool sizes (1-2 g, 2-3 g, 3-4 g, and >4 g). Factors that should regulate pool size are synthesis, absorption efficiency, and cycling frequency of the pool. In subjects with relatively low pools, steady state synthesis and absorption of bile acids were not reduced. However, two other factors appeared to be especially important in keeping pool sizes in the lower ranges--a high cycling frequency and overly sensitive feedback inhibition of bile acid synthesis. First, there was a significant inverse correlation between cycling frequency and pool size. Theoretically, a high cycling frequency should reduce pools in two ways--by suppressing synthesis and by increasing fecal losses. Second, in patients with low pools, transhepatic flux of bile acids was also reduced, and daily synthesis of bile acid, although being in the same range as those with larger pools, was inappropriate for the magnitude of the flux. With this overactive feedback on bile synthesis, these patients were unable to increase their bile acid synthesis to supranormal levels so as to cause a reexpansion of the pool to higher levels.

GENERAL

Parasitology

1676 HUMAN CHRONIC MANSONIAN SCHISTOSOMIASIS--CELL PROLIFERATION AND FIBRE FORMATION IN THE HEPATIC SINUSOIDAL WALL: A MORPHOMETRIC, LIGHT AND ELECTRON-MICROSCOPY STUDY. (Eng.) Canto, A. L.; Sesso, A.; De Brito, T. (Faculdade de Medicina de Sao Paulo, Sao Paulo Univ., Sao Paulo, Brazil). *J. Pathol.* 123(1):35-44; 1977.

The correlation between sinusoidal cells and reticulin fiber proliferation was studied in human chronic schistosomiasis mansoni. A morphometric, light and electron microscopic study of the sinusoids in biopsy or necropsy specimens from 10 patients without hepatic disease, and 19 patients with schistosomiasis (10 with the intestinal form not exhibiting hypertension, and 9 with the hypertensive, hepatosplenic form) showed a sequence of events beginning with an increased number of cell nuclei, particularly evident at the centrilobular region. This was followed by deposition of reticulin fibers along the perisinusoidal space. Later, increased numbers of cells and reticulin fibers were seen throughout the lobule. Other findings, such as reduplication of the sinusoidal lining and the focal appearance beneath the cell layer of the thin discontinuous membrane, also occurred. This perisinusoidal fibrosis may add an element of heightened intrasinusoidal pressure to the perisinusoidal hypertension already present. The hepatic sinusoids in schistosomiasis mansoni receive mainly arterial blood. High intraluminal pressure may be one explanation of the perisinusoidal fibrosis in these cases. However, as it possibly occurs in primary sinusoidal portal hypertension, chronic immunological stimulation leading to proliferation of Kupffer cells and lipocytes may be an alternative mechanism. Whatever the pathogenetic mechanism, the livers of patients with chronic schistosomiasis mansoni exhibit a progressive sinusoidal reaction to injury.

1677 CONTROL OF Schistosoma mansoni TRANSMISSION BY CHEMOTHERAPY IN ST. LUCIA. I. RESULTS IN MAN. (Eng.) Cook, J. A.; Jordan, P.; Bartholomew, R. K. (Ministry Health, P.O. Box 93, Castries, St. Lucia, West Indies). *Am. J. Trop. Med. Hyg.* 26(5, Part 1):887-893; 1977.

Two-year results of a program for the control of schistosomiasis in St. Lucia are presented. *Schistosoma mansoni* transmission was controlled by treating all infected persons in Marquis Valley (population about 3,100), St. Lucia with hycanthone; children under 3 yr or weighing less than 15 kg received niridazole or lucanthone hydrochloride. Excluding 26 pregnant patients, 709 of 729 persons who were found to be infected received treatment the first year. Six hundred and seventy-seven patients were given a single injection of hycanthone (2.5 mg/kg), and the same treatment was administered to 150 patients in the second year. Side-effects were not severe; the major side-effect, vomiting, occurred in about 22% on both occasions. In villages with initially high transmission rates, the incidence of new infections in children 0 to 14 yr fell from 20.8% before chemotherapy to 7.4% after 1 yr and to 3.7% after 2 yr. This pattern was significantly different from that in the comparison area where no control scheme exists. Chemotherapy alone appears to be a rapid effective, and comparatively inexpensive method of controlling *S. mansoni* transmission in St. Lucia.

678 CONTROL OF Schistosomiasis mansoni TRANSMISSION BY CHEMOTHERAPY IN ST. LUCIA. II. IOLOGICAL RESULTS. (Eng.) Christie, J. D.; Upa-ham, E. S. (Ministry Health, P.O. Box 93, Castries, St. Lucia, West Indies). *Am. J. Trop. Med. Hyg.* 26 (5, Part 1):894-898; 1977.

Studies were carried out to determine whether a schistosomiasis chemotherapy program had any effect on infection rates in the intermediate snail host in St. Lucia, *Biomphalaria glabrata*. Chemotherapy of all persons infected with *Schistosoma mansoni* was begun in Marquis Valley, St. Lucia, in March 1974. From January 1972 to the start of chemotherapy, the infection rate in field *B. glabrata* collected in the valley was 1.09% (117/10,736), and the rate in sentinel *B. glabrata* was 1.48% (56/3,790). From March 1974 through December 1975, no infections were detected in either field snails (11,742 collected) or sentinel snails (3,230 exposed). The accumulated data suggest that, because of differences in topography and average annual rainfall, *S. mansoni* transmission occurs in this valley during the rainy season, whereas in other St. Lucian valleys under study it occurs during the dry season.

1679 A STUDY OF THE PRESENCE OF CIRCULATING IMMUNE COMPLEXES IN SCHISTOSOMIASIS. (Eng.) Smith, M. D.; Verroust, P. J.; Morel-Maroger, L.; Geniteau, M.; Coulaud, J. P. (Hopital Tenon, 75020 Paris, France). *Trans. R. Soc. Trop. Med. Hyg.* 71(4):343-348; 1977.

The sera of 51 patients with schistosomiasis were studied for the presence of circulating immune complexes (IC) using two methods, inhibition of complement-coated sheep RBC-anti Ig complex (EAC) rosette formation and precipitation of radiolabeled complement component Clq (Clq). The percentage EAC rosette inhibition was significantly greater in the total group of patients compared to the control sera. The material inhibiting EAC rosette formation was precipitable by 4% polyethylene glycol, thus excluding the role of C3 fragments and suggesting that inhibition was due to immune complexes. Using precipitation of radiolabeled Clq, significantly high values compared to control sera were only obtained in those patients before treatment or with an active infection (p=0.003). The results suggest that material behaving as IC is present in the sera of patients with schistosomiasis and that measurement of the levels of IC may be important in assessing the state of the disease.

1680 IMMUNE RESPONSES DURING HUMAN SCHISTOSOMIASIS MANSONI. II. OCCURRENCE OF EOSINOPHIL-DEPENDENT CYTOTOXIC ANTIBODIES IN RELATION TO INTENSITY AND DURATION OF INFECTION. (Eng.) Sher, A.; Butterworth, A. E.; Colley, D. G.; Cook, J. A.; Freeman, G. L., Jr.; Jordan, P. (Harvard Medical Sch., 250 Longwood Ave., Boston, MA 02115). *Am. J. Trop. Med. Hyg.* 26(5, Part 1): 909-916; 1977.

Plasma samples from St. Lucians were tested for the presence of antibodies that cooperate *in vitro* with normal human WBC in causing cytotoxic damage to schistosomula of *Schistosoma mansoni*. The *in vitro* antibody activity, which has been previously shown to depend on eosinophil effector cells, was detected in 56% of the individuals with known, current *S. mansoni* infections and in 14% of control subjects from the same endemic area. Quantitatively, eosinophil dependent cytotoxic antibody (EDCA) activity, when expressed as the maximum amount of damage to schistosomula induced at high plasma concentration, correlated significantly with the intensity of *S. mansoni* infection as determined by fecal egg count, the highest levels of activity occurring in patients with stool counts of 60 eggs/ml or greater. In addition, plasma EDCA activity correlated with the *in vitro* blastogenic responsiveness of patients' lymphocytes to three different parasite antigen preparations. In contrast, titrations of EDCA activity failed to reveal a relationship between EDCA titer and the most recent egg count performed on each subject. However, a significant correlation was observed when titers were compared to egg counts averaged over a 3-yr period. Neither maximal EDCA activity nor titer correlated with the duration of known schistosome infection.

1681 IMMUNE RESPONSES DURING HUMAN SCHISTOSOMIASIS MANSONI. III. REGULATORY EFFECT OF PATIENT SERA ON HUMAN LYMPHOCYTE BLASTOGENIC RESPONSES TO SCHISTOSOME ANTIGEN PREPARATIONS. (Eng.) Colley, D. G.; Hieny, S. E.; Bartholomew, R. K.; Cook, J. A. (Veterans Admin. Hosp., Nashville, TN 37203). *Am. J. Trop. Med. Hyg.* 26(5, Part 1):917-925; 1977.

The capability for *in vitro* blastogenesis of lymphocytes from 38 patients with schistosomiasis mansoni was tested against phytohemagglutinin (PHA), *Candida albicans* extract, and soluble preparations of schistosome eggs (SEA), adult worms (SWAP), or cercariae (CAP). When patients' lymphocytes were cultured in medium that contained 5% human (homologous) normal (uninfected) serum, they responded well to PHA and *Candida* extract. The responses induced by SEA were maximal in patients with early *Schistosoma mansoni* infections, while reactivity against SWAP and CAP increased during chronic infection. These responses, induced by the schistosome-derived antigenic preparations, were suppressed if the homologous-normal serum supplement of the culture medium was replaced with either the patient's own (autologous) serum, or that of another patient infected with *S. mansoni*. All sera were heat-inactivated (56 C for 30 min) prior to use. In contrast, responses against the nonspecific mitogen (PHA) and the unrelated antigen (*Candida* extract), were not altered by these changes of the serum supplementation of the media. The degree of suppression by patient serum was not changed by increasing the serum percentage in the medium from 5% to 25%. The suppressive effects of patient sera on responses induced by SEA and SWAP were increased in relation to the duration of the serum donor's *S. mansoni* infection. Preincubation of lymphocytes in suppressive patient sera for 30 min at 37 C did not reduce the expected level of responsiveness if the cells were subsequently cultured in homologous-normal serum supplemented medium. The data indicate that during *S. mansoni* infection, patients develop serum component(s) that specifically interfere with the responsiveness of their lymphocytes in regard to certain schistosome-derived antigenic preparations. The immunoregulatory events described could participate in the modulation of immunopathology, the maintenance of chronic adult worm survival, and the prevention of full expression of protective immune responses.

GENERAL

Regional Enteritis

1687 CROHN'S DISEASE INVOLVING THE COLON: AN AUDIT OF CLINICAL MANAGEMENT. (Eng.) Allan, R.; Steinberg, D. M.; Williams, J. A.; Cooke, W. T. (General Hosp., Birmingham B46NH, England). *Gastroenterology* 73(4, Part 1):723-732; 1977.

The clinical management of 204 patients with Crohn's disease involving the colon who have been reviewed at 3- to 6-month intervals for up to 34 yr (mean 13.1 ± 8.7 yr) are described. The results were analyzed to define the morbidity, mortality, and long-term prognosis of the disorder. Despite a high morbidity, the long-term prognosis was good. Although the mean interval since the onset of symptoms was more than 13 yr, 77% of the patients were symptom-free and 60% had normal laboratory indices. This analysis suggests that until the etiology of Crohn's disease is established and a specific therapy is developed, good results can be obtained with regular medical review and appropriate surgical treatment with the limited use of corticosteroids and the minimal use of immunosuppressive agents or total parenteral nutrition.

1688 SELECTIVE IgA DEFICIENCY AND CROHN'S DISEASE: REPORT OF TWO CASES. (Eng.) Hodgson, H. J. F.; Jewell, D. P. (Royal Free Hosp., London, England). *Gut* 18(8):644-646; 1977.

Two patients with Crohn's disease and selective IgA deficiency are described. Serum IgA was undetectable in each case, and immunoperoxidase studies of the lamina propria showed a gross diminution of IgA-bearing plasma cells. Peripheral blood lymphocytes, however, showed normal numbers of IgA-bearing lymphocytes (2.3% and 6.8% of total lymphocytes in each patient, resp.). The typical clinical course and histology in these two patients suggest that IgA-mediated responses in the mucosa are not involved in the pathogenesis of Crohn's disease.

1689 HLA AND B-CELL ANTIGENS IN PATIENTS WITH CROHN'S DISEASE [Abstract]. (Eng.) Cohen, Z.; Wolfe, E.; Papasteriadis, C.; Werner, C.; Festenstein, H. (London Hosp. Medical Coll., London, England). *Clin. Res.* 25(5):687A; 1977.

PREFACE

GASTROENTEROLOGY ABSTRACTS and CITATIONS is a publication of the National Institute of Arthritis, Metabolism and Digestive Diseases. This specialized information medium has been initiated to fill an existing great need in the field of gastroenterology and to assist the Institute in meeting its obligations to foster and support laboratory and clinical research into the nature, causes, and therapy of diseases of the gastrointestinal tract. Publication GASTROENTEROLOGY ABSTRACTS and CITATIONS makes available citations of all current papers relevant to this field from medical journals published throughout the world. Approximately one-third of the citations dealing with the major aspects of gastroenterology have accompanying abstracts.

The issuing of GASTROENTEROLOGY ABSTRACTS and CITATIONS under the auspices of the National Institute of Arthritis, Metabolism, and Digestive Diseases will provide a much needed current awareness tool to scientists and will facilitate greater integration of research and clinical efforts in this field. The number and great diversity of publications in the area of gastroenterology makes it imperative that an appropriate service be available to investigators and practitioners so that they may be apprised of progress with a minimum of delay. Our aim is to provide the readers with a readily systematized compilation of current published work. The publication will provide the greatest usefulness if these interested investigators will contribute their ideas and comments for consideration whenever possible.

GASTROENTEROLOGY ABSTRACTS and CITATIONS is published monthly and includes citations and abstracts from the biomedical world literature as they are currently received. In addition, yearly cumulated subject and author indexes are published.

This publication is available free to National Institutes of Health grantees and contractors working in the field of gastroenterology and libraries of medical schools. Requests from these qualified individuals to receive free copies of this publication must include their grant or contract number and the title of their project. These requests as well as address changes and other communications should be addressed to:

Scientific Communications Officer
Gastroenterology Abstracts and Citations
National Institute of Arthritis, Metabolism and Digestive Diseases
National Institutes of Health
Building 31, Room 9A-21
Bethesda, Maryland 20014

Other individuals and libraries may receive this publication by subscribing *directly* to the Superintendent of Documents, U.S. Government Printing Office, Washington, D.C. 20402. Subscription price per year in the United States and its possessions: $27.00 (this includes index issue); foreign, $6.75 additional. Single copy price is $1.90 domestic and $2.40 foreign. The index issue is $3.45 domestic and $4.35 foreign. Payment is required in advance, and check or money order should be made payable to the Superintendent of Documents.

AUTHOR INDEX		
SUBJECT INDEX		

The Secretary of the Department of Health, Education, and Welfare has determined that the publication of this periodical is necessary in the transaction of the public business required by law of this Department. Use of funds for printing this periodical has been approved by the Director of the Office of Management and Budget through April 30, 1981.

For sale by the Superintendent of Documents, U.S. Government Printing Office, Washington, D.C. 20402. Subscription price per year in the United States and its possessions: $27.00 (this includes index issue); foreign, $6.75 additional. Single copy price is $1.90 domestic and $2.40 foreign. The index issue is $3.45 domestic and $4.35 foreign. Payment is required in advance, and check or money order should be made payable to the Superintendent of Documents.

NOTE

Journal names are abbreviated according to the list of abbreviations used by *Index Medicus*. For journals not covered by *Index Medicus*, the abbreviations (with some modifications) found in *International Standard ISO833, 1974*, are used. The two-letter state abbreviations are based on the United States Postal Service Code.

ABBREVIATIONS USED IN ABSTRACTS

ACTH	adrenocorticotropic hormone
ADP	adenosine diphosphate
AMP	adenosine monophosphate
amp	ampere
ATP	adenosine triphosphate
A	angstrom
BSP	sulfobromophthalein
C	degrees centigrade
cal	calories
cc	cubic centimeter
cm	centimeter(s)
dl	deciliter
DNA	deoxyribonucleic acid
ED$_{50}$	median effective dose(s)
EDTA	ethylenediamine tetraacetic acid
e.g.	for example
EEG	electroencephalogram
ESR	erythrocyte sedimentation rate
g	gram(s)
μg	microgram(s)
Hz	Hertz
hr	hour(s)
Ig	immunoglobulin(s)
i.m.	intramuscular
i.p.	intraperitoneal
IU	international unit(s)
i.v.	intravenous
kcal	kilocalorie(s)
kg	kilogram(s)
K$_m$	Michaelis constant
LD$_{50}$	median lethal dose(s)
LDH	lactic acid dehydrogenase
m	meter(s)
M	molar; mole(s)
mM	millimolar; millimole(s)
μM	micromolar; micromole(s)
ma	milliampere(s)
mCi, μCi	milli-, microcurie(s)
mEq	milliequivalent(s)
mg	milligram(s)
ml, μl	milli-, microliter(s)
mm	millimeter(s)
mOsm	milliosmolar; milliosmeter(s)
msec	millisecond(s)
mV	millivolt(s)
min	minute(s)
MTD	maximum tolerated dose
NAD	nicotinamide adenine dinucleotide
NADH	reduced nicotinamide adenine dinucleotide
NADP	nicotinamide adenine dinucleotidephosphate
NADPH	reduced nicotinamide adenine dinucleotidephosphate
ng	nanogram (10^{-9})
nm	nanometer(s)
Pa	ambient pressure
PAS	periodic acid - Schiff
pg	picogram (10^{-12})
pgEq	picogram equivalent(s)
p.o.	orally
ppb	parts per billion
ppm	parts per million
r	Roentgen
RBC	red blood cells (erythrocytes), red blood count
resp.	respectively
RNA	ribonucleic acid
s.c.	subcutaneous
sec	second(s)
SGOT	serum glutamic-oxalacetic transaminase
SGPT	serum glutamic-pyruvic transaminase
U	unit(s)
UV	ultraviolet
V	volt
WBC	white blood cells (leukocytes), white blood count
yr	year(s)

MORPHOLOGY, CELLULAR STRUCTURE AND HISTOCHEMISTRY

1694 SMALL BOWEL MORPHOLOGY AND EPITHELIAL PROLIFERATION IN INTRAVENOUSLY ALIMENTED RABBITS. (Eng.) Eastwood, G. L. (West Roxbury Veterans Admin. Hosp., 1400 Veterans of Foreign Wars Parkway, West Roxbury, MA 02132). *Surgery* 82(5):613-620; 1977.

To determine whether alterations in epithelial renewal accompany the morphological changes observed in experimental animals on i.v. alimentation, cell proliferation and the light and electron microscopic appearance of the small bowel were investigated in i.v. and p.o. alimented rabbits. After 10 days of either i.v. or p.o. alimentation, ^{3}H-thymidine was given i.v. to all animals, and 1 hr later sections of duodenum, upper jejunum, and distal ileum were taken for autoradiography and light and electron microscopy. Parenteral alimentation was accompanied by significant reductions in epithelial cell proliferation and mucosal thickness in the proximal small bowel. The density of goblet cells was greater in the duodenum and jejunum, but less in the ileum, of i.v. alimented rabbits than in corresponding areas of the animals fed p.o. Furthermore, ultrastructural changes in the villous absorptive cells of i.v. alimented rabbits, such as lengthened microvilli and increased numbers of multivesicular bodies, suggest that epithelial migration also may be slowed during parenteral alimentation.

1695 THE EFFECT OF INTESTINAL RESECTION ON THIRY-VELLA FISTULAE OF JEJUNAL AND ILEAL ORIGIN IN THE RAT: EVIDENCE FOR A SYSTEMIC CONTROL MECHANISM OF CELL RENEWAL. (Eng.) Hanson, W. R.; Rijke, R. P. C.; Plaisier, H. M.; Van Ewijk, W.; Osborne, J. W. (Div. Biological and Medical Res., Argonne Natl. Lab., Argonne, IL 60439). *Cell Tissue Res.* 10(6):543-555; 1977.

To test the hypothesis that steady state cell renewal in the intestinal epithelium is maintained by a systemic, rather than a local, mechanism, the effect of 60% mid-intestinal resection on Thiry-Vella fistulae of both jejunal and ileal origin was studied in rats. Hypoplasia occurred in fistulae without resection of the remaining intestine in continuity. Cell counts of crypt and villus columns and tritiated thymidine uptake in isolated whole crypts were reduced. Scanning electron microscopy showed marked hypoplastic alterations in villi. However, when 60% of the intestine in continuity was resected, hyperplasia occurred not only in the residual intestine but in the fistulae of both jejunal and ileal origin. Cell counts of villus and crypt columns were increased along with increased tritiated thymidine uptake per crypt. Neutral α-glucosidase and nonspecific esterase activities did not change as a result of resection, but the activities of both enzymes were greater in ileal fistulae than in ileum *in situ*. Observations on the different resection response of the jejunal versus ileal fistulae lead to a distinction between inherent and induced differences within the small intestine. This study suggests a systemic control of cell renewal.

1696 MORPHOLOGICAL CHANGES INDUCED BY CYCLOPHOSPHAMIDE IN CRYPT EPITHELIUM OF THE SMALL INTESTINE IN MICE: LIGHT AND ELECTRON MICROSCOPIC STUDIES. (Eng.) Sobhon, P.; Wanichanon, C.; Sretarugsa, P. (Dept. Anatomy, Mahidol Univ., Rama VI Rd., Bangkok 4, Thailand). *Am. J. Anat.* 149(4):563-584; 1977.

The extent of mitotic inhibition and cellular injury in the intestinal crypts were studied in female Swiss mice following the i.p. injection of a single sublethal dose (300 mg/kg) of cyclophosphamide. Within 1 hr, light microscopic observations indicated that mitotic activity of epithelial cells had decreased, reaching the lowest level at 16 hr. An abnormally high number of lymphocytes and cells with eosinophilic granules appeared in the epithelium; later these cells degenerated, and the maximum number of dead cells was observed at 6 hr after the drug injection. At 4 days post-injection, the morphology of crypt epithelium had returned to normal. Electron microscopy revealed that, although the mitotic activity of crypt epithelial cells was depressed, there was little change in their morphology following the drug administration. However, many intermediate stages of degeneration of lymphocytes and eosinophilic cells were observed in the intercellular spaces as well as apparently inside the cytoplasm of crypt epithelial cells. The eosinophilic cells are characterized by the presence of large crystal-containing granules in the cytoplasm, and are believed to be equivalent to "globular leukocytes" described by many investigators. Evidence from this study suggests that lymphocytes and globular leukocytes are more sensitive to cyclophosphamide than are crypt epithelial cells, and that they degenerate in crypt epithelium.

1697 HUMAN ROTAVIRUS ENTERITIS INDUCED IN CONVENTIONAL PIGLETS: INTESTINAL STRUCTURE AND TRANSPORT. (Eng.) Davidson, G. P.; Gall, D. G.; Petric, M.; Butler, D. G.; Hamilton, J. R. (Hosp. Sick Children, Toronto, Ontario, Canada). *J. Clin. Invest.* 60(6):1402-1409; 1977.

To better understand the pathogenesis of infantile viral gastroenteritis, Na^+ and Cl^- fluxes were studied *in vitro* in short-circuited jejunal epithelium from 8- to 10-day-old piglets after infection with a standard p.o. dose of human rotavirus. Eleven infected piglets, all of whom became ill, were compared with nine uninfected, healthy littermates. When killed 72 hr after infection, the intestinal villi were shorter and crypts deeper ($p<0.025$) in the duodenum, upper jejunum, and mid-small intestine, but not ileum, as compared to control tissue. Virus antigen was seen by fluorescence microscopy in occasional jejunal villus tip cells in only four infected piglets and in none of the controls at 72 hr. Net Na^+ and Cl^- fluxes did not differ from noninfected litter-mate controls under basal conditions, but the response to glucose was blunted in infected piglets ($p<0.001$). Theophylline-stimulated net Cl^- secretion in both infected and control animals, and cyclic AMP concentration in isolated jejunal villus enterocytes did not differ significantly. In isolated jejunal villus enterocytes of infected piglets, thymidine kinase activity increased ($p<0.001$), and sucrase activity decreased ($p<0.001$). It is concluded that in invasive enteritis caused by a major human viral pathogen, glucose-coupled Na^+ transport is impaired in the jejunum at a time when the villus epithelium shows enzyme characteristics of crypt epithelium, and when little or no virus is present. These findings are identical to those occurring in an invasive coronavirus enteritis of piglets but differ markedly from those seen with enterotoxigenic diarrhea.

1698 IMMUNO-ELECTRON-CYTOCHEMICAL LOCALIZATION OF THE SOMATOSTATIN CELLS IN THE HUMAN ANTRAL MUCOSA.

(Eng.) Canese, M. G.; Bussolati, G. (Istituto di Anatomia e Istologia Patologica, Univ. Turin, Turin, Italy). *J. Histochem. Cytochem.* 25(10):1111-1118; 1977.

Specific immunocytochemical and light and electron microscopic methods were used to identify the somatostatin-containing cells of the human antral mucosa. By means of immunoperoxidase and immunofluorescence methods sequentially applied on the same section, the somatostatin cells were shown to be distinct from the gastrin cell population; these two endocrine cell types were often closely related. On ultrathin sections from aldehyde-fixed, Epon-araldite embedded tissues, the site of storage of somatostatin was localized with the peroxidase-antiperoxidase complexes technique after removal of the resin by means of sodium ethoxide. This procedure represents a new technical approach to the use of electron-cytochemical techniques. The results indicate that somatostatin is localized in the endocrine granules of the D cells.

1699 SUBSEGMENTATION OF THE HUMAN LIVER.

(Eng.) Gupta, S. C.; Gupta, C. D.; Arora, A. K. (Dept. Anatomy, S.N. Medical Coll., Agra, India). *J. Anat.* 124(2):413-423; 1977.

The normal topographical arrangement of human hepatic subsegments, with special reference to abnormal variations, was examined in 85 livers obtained within 24 hr of death from subjects of all ages. Colored corrosion casts of the portal vein, hepatic duct, and hepatic artery were prepared with applications of colored 18% butyl butyrate solution in acetone. Hepatic subsegments were identified by the independence of their vessels and ducts from those of neighboring territories. The following hepatic subsegments were distinguished: (1) posterior, (2) posterior inferior, (3) anterior superior, (4) anterior inferior, (5) medial superior, (6) medial inferior, (7) lateral superior, (8) lateral inferior, and (9) caudate. The sizes of the subsegments were very similar in 41 cases (48.2%). In the others, some increase or decrease in size of one or more subsegments at the expense of the neighboring subsegments was observed. Resection of a portion of the liver should not be performed without previous identification of hepatic subsegments by cholangiography or portovenography.

1700 MORPHOLOGICAL EXAMINATION OF ESOPHAGUS STOMACH AND ESOPHAGUS INTESTINE ANASTOMOSES FOLLOWING PREOPERATIVE RADIATION THERAPY.

(Ger.) Izabekov, Z. B.; Kolyceva, N. I.; Chan, S. V.; *et al.* (Kazakhstan Scientific Res. Inst. Oncology, Radiology, Alma Ata, USSR). *Radiobiol. Radiother. (Berl.)* 17(2):305-312; 1976.

1701 THE EVOLUTION OF MUCOSAL CHANGES IN EXPERIMENTAL GASTROESOPHAGEAL REFLUX ON HISTOPATHOLOGY AND SURFACE MICROSCOPY [Abstract].

(Eng.) Schulze, K.; Mitros, F.; Christensen, J.; Shirazi, S.; Ackerman, L. (Coll. Medicine, Univ. Iowa, Iowa City, IA 52242). *Clin. Res.* 25(4):574A; 1977.

1702 STRUCTURE AND FUNCTION OF THE MOUSE SMALL INTESTINE AFTER INFECTION WITH Schistosoma mansoni [Abstract].

(Eng.) Vengesa, P. B.; Leese, H. J. (Dept. Biology, Univ. York, York, England). *Gut* 18(11):A965-A966; 1977.

1703 ENDOSCOPIC OBSERVATION OF THE GASTRIC MUCUS IN VIVO STAINED WITH AZURE A.

(Eng.) Kamada, T.; Hiramatsu, K.; Fusamoto, H.; *et al.* (Osaka Univ. Medical Sch., Osaka, Japan). *Am. J. Gastroenterol.* 65(6):532-538; 1976.

1704 PARACELLULAR PERMEABILITY OF EXTRACELLULAR SPACE MARKERS ACROSS RAT JEJUNUM IN VITRO. INDICATION OF A TRANSEPITHELIAL FLUID CIRCUIT.

(Eng.) Munck, B. G.; Rasmussen, S. N. (Inst. Medical Physiology A, Univ. Copenhagen, Copenhagen, Denmark). *J. Physiol. (Lond.)* 271(2):473-488; 1977.

The characteristics of [^{51}Cr]EDTA, [^{3}H]methoxyinulin ([^{3}H]MI), [^{14}C]polyethylene glycol-4000 ([^{14}C]PEG), and [^{3}H]mannitol as markers of the extracellular space (ECS) of isolated mucosa from the rat small intestine were examined. Unidirectional transmural fluxes across the rat jejunum of [^{3}H]MI, [^{14}C]PEG, and [^{3}H]mannitol were measured in the absence of glucose or in the presence of 28 mM glucose. Assuming that [^{14}C]PEG does not enter the cells, [^{51}Cr]EDTA and [^{3}H]mannitol seemed to have access to approximately 50% and 90% of the intracellular water, resp. The commercially available [^{3}H]MI had access to a space that exceeded the [^{14}C]PEG space by 10%. Upon purification by gel filtration, the high molecular weight fraction of the [^{3}H]MI provided estimates of the ECS identical with the estimates obtained with [^{14}C]PEG. For all the markers used, the ECS estimates remained constant between the 40th and 80th min of incubation. In the absence of glucose, the transepithelial net fluxes of each of the different markers were zero. In the presence of 28 mM glucose, the serosa-to-mucosa fluxes of all markers were dramatically increased. The ratio between the serosa-to-mucosa and the mucosa-to-serosa fluxes increased in the order [^{3}H]mannitol>[^{3}H]MI>[^{14}C]PEG. The effect of glucose on the flux ratio of the marker substances suggests that glucose-induced net water transport to the serosal side of the gut wall represents the difference between a transcellular net water transport to the serosal side and a significant paracellular net water transport through the lateral intercellular spaces to the mucosal solution.

1705 THE IMPORTANCE OF THE INTESTINAL COUNTERCURRENT EXCHANGER FOR ^{85}Kr ABSORPTION FROM THE FELINE GUT.

(Eng.) Jodal, M.; Svanik, J.; Lundgren, O. (Dept. Physiology, Univ. Goteborg, Goteborg, Sweden). *Acta Physiol. Scand.* 100(4):412-423; 1977.

The relationships between intestinal absorption rate and blood flow and between absorption rate and intraluminal pressure were studied in cats. The rate of ^{85}Kr absorption from the gut was studied at varying intestinal blood flows induced by intra-arterial infusions of a vasodilator drug or by lowering arterial inflow pressure. The effects on rate of absorption of distending the intestine by increasing intraluminal pressure from 0-1 to 5-7 cm H_2O as well as of augmenting the rate of luminal perfusion of the ^{85}Kr solution were also investigated. Distending the small bowel increased rate of ^{85}Kr absorption at all levels of intestinal blood flow except at the very low and the very high blood flow rates. Decreasing blood flow by lowering the arterial perfusion pressure decreased the rate of absorption from the distended gut while it had no effect in the collapsed small intestine. Increasing the rate of luminal perfusion enhanced the rate of ^{85}Kr absorption at all blood flow levels except at the lowest ones. It is concluded that the countercurrent exchanger represents, under physiological conditions, the major limiting factor for the absorption of lipophilic solutes such as ^{85}Kr.

1706 THE ROLE OF ACETYLCHOLINE IN THE REGULATION OF ION TRANSPORT BY RAT COLON MUCOSA.

(Eng.) Browning, J. G.; Hardcastle, J.; Hardcastle, P. T.; Sanford, P. A. (Dept. Physiology, Univ. Sheffield, Sheffield, England). *J. Physiol. (Lond.)* 272(3): 737-754; 1977.

The possibility that colonic ion transport mechanisms might be under cholinergic control was investigated by determining the effect of acetylcholine on the transport activity of the rat colon. Acetylcholine (3 µg i.v. *in vivo*; 25 mM *in vitro*) increased the potential difference across rat proximal colon. There was a sigmoid relationship between the change in potential difference and the logarithm of the dose of acetylcholine. The dose-response curve was shifted to the left *in vivo* by neostigmine (10 µg) and to the right by atropine (2 µg), suggesting that the action of acetylcholine is mediated by a muscarinic type of receptor. The dose-response curve for acetylcholine *in vivo* was not altered by the ganglion-blocking agents hexamethonium (100 µg) and pentolinium (25 µg), suggesting a direct effect of this transmitter on the colon. Acetylcholine caused an increase in potential difference, a small decrease in resistance, and, hence, a rise in the current generated by both normal and stripped everted sacs of rat colon. In the absence of sodium, the calculated current change produced by acetylcholine was reduced, and the removal of chloride had a similar inhibitory effect. The absence of bicarbonate did not significantly affect the response. Acetylcholine virtually abolished net sodium movement and induced net chloride secretion, and these changes accounted for the increased short-circuit current. Acetylcholine had no effect on oxygen consumption by rings of colon. Tracts staining for acetylcholinesterase were observed running from the submucous plexus towards the mucosal epithelium. The results demonstrate that acetylcholine can influence ion movement by rat colonic mucosa and suggest that the autonomic nervous system might be involved in the regulation of transport mechanisms in this tissue.

1707 THE EFFECT OF ETHANOL AND BILE ON ELECTROLYTE MOVEMENT ACROSS CANINE PROXIMAL DUODENAL MUCOSA.

(Eng.) Himal, H. S.; Greenberg, L. (Royal Victoria Hosp., 687 Pine Ave. W., Montreal, Quebec H3A 1A1, Canada). *Am. J. Gastroenterol.* 68(1):45-50; 1977.

The effect of ethanol and bile on electrolyte movement across the duodenal mucosa was examined in 10 dogs. Duodenal explants from the dogs with an intact blood supply were placed within lucite chambers. Under basal conditions there was H$^+$ insorption and Na$^+$ exsorption. Neither bile nor ethanol (20%) caused increased the H$^+$ Na$^+$ flux. Acute erosions did not develop in the proximal duodenum, as has been previously shown to occur when bile or ethanol is instilled into the stomach. These studies demonstrate that although H$^+$ Na$^+$ flux occurs across the duodenal mucosa, bile or ethanol do not cause changes in ionic flux and acute erosions do not develop.

1708 ALTERATION OF LARGE INTESTINAL ELECTROLYTE TRANSPORT BY VASOACTIVE INTESTINAL POLYPEPTIDE IN THE RAT. (Eng.) Racusen, L. C.; Binder, H. J. (Dept. Internal Medicine, Yale Univ., 333 Cedar St., New Haven, CT 06510). *Gastroenterology* 73(4, Part 1):790-796; 1977.

The effect of vasoactive intestinal polypeptide (VIP) on Na and Cl transport across isolated large intestinal epithelia under short-circuited conditions was evaluated in the rat, since some evidence suggests that this intestinal hormone may not affect colonic ion transport. An increase in short-circuit current and potential difference was produced by the addition of VIP to the serosal media at concentrations as low as 10^{-9} M, and maximal increments were observed at 10^{-7} M. In control mucosa, the net sodium flux was 4.93 ± 0.52 μEq/hr/cm^2. The addition of VIP (6 x 10^{-7} M) resulted in a decrease in net sodium flux (0.87 ± 0.46 μEq/hr/cm^2), a reversal of Cl absorption to Cl secretion (-2.42 ± 1.12 μEq/hr/cm^2), and an increase in short-circuit current. Unidirectional mucosal to serosal fluxes of both Na and Cl decreased. The changes produced by VIP were identical with those induced by 10 mM theophylline. The effect of VIP plus theophylline on the net sodium flux and short-circuit current were indistinguishable from those of VIP alone and theophylline alone. VIP also increased mucosal cyclic AMP content. These studies indicate that VIP alters large intestinal ion transport; these changes are most likely mediated by increased mucosal levels of cyclic AMP.

1709 ADENOSINE UPTAKE BY THE ISOLATED EPITHELIUM OF GUINEA PIG JEJUNUM. (Eng.) Kolassa, N.; Stengg, R.; Turnheim, K. (Pharmakologisches Institut, Universitat Wien, Wahringerstr. 13A, A-1090 Vienna, Austria). *Can. J. Physiol. Pharmacol.* 55(5):1033-1038; 1977.

The respective roles of passive diffusion and of carrier-mediated transfer in the uptake of adenosine by the intestinal epithelium were studied in the isolated guinea pig jejunal epithelium. The uptake of [8-^{14}C]adenosine was faster than that of inosine, hypoxanthine, or adenine. The initial velocity of adenosine uptake from both the luminal and the antiluminal side of the epithelium exhibited saturation kinetics. The apparent K_m, V, and passive permeability of luminal adenosine uptake were all lower than the corresponding values of antiluminal uptake. *p*-Nitrobenzylthioguanosine inhibited adenosine uptake from both the luminal and the antiluminal side, while hexobendine decreased the uptake only from the antiluminal side of the epithelium. The results suggest that adenosine enters the intestinal epithelium by a carrier-mediated process in addition to that of passive diffusion. The antiluminal transport system for adenosine seems similar to that of other tissues with respect to hexobendine inhibition; the luminal transport mechanism, however, exhibits different properties, being insensitive to hexobendine.

1710 AMINO ACID ABSORPTION ALONG THE INTESTINAL TRACT OF CHICKS FED HEATED AND RAW SOYBEAN MEAL. (Eng.) Bielorai, R.; Tamir, M.; Hurwitz, S. (Inst. Animal Sciences, Agricultural Res. Organization, Volcani Center, Bet Dagan, Israel). *J. Nutr.* 107(10):1775-1778; 1977.

Net absorption of individual amino acids along the intestinal tract was determined in chicks fed heated soybean meal (HS) and raw soybean meal (RS), using ^{91}Y as a reference substance. In the duodenum of chicks fed either diet, the absorption of the amino acids varied. In chicks fed the RS diet, the differences were greater than in chicks fed the HS diet, and most of the values were negative. Methionine was the most rapidly and extensively (82%) absorbed amino acid. No cystine was found in the upper parts of the intestinal tract of chicks fed either diet. A linear relationship was obtained between the amino acid absorption values in the duodenum of chicks fed either diet. The differences may be due to nitrogen secretion, which is known to be enhanced in RS-fed chicks. The differences between individual amino acid absorption decreased gradually in the other segments and attained in the lower ileum an average cumulative value of 90% and 70% in chicks fed on HS and RS, resp. The 20% difference is probably a result of the inhibited digestion in the intestine (duodenum excluded) of chicks fed RS. The results indicate that absorption can proceed even when digestion is inhibited.

1711 A REAPPRAISAL OF 'OSMOTIC' EVIDENCE FOR INTACT PEPTIDE ABSORPTION. (Eng.) Fairclough, P. D.; Silk, D. B.; Webb, J. P. W.; Clark, M. L.; Dawson, A. M. (St. Bartholomew's Hosp., London EC1A 7BA, England). *Clin. Sci. Mol. Med.* 53(3):241-248; 1977.

The validity of evidence for intact peptide absorption, derived from analysis of the relation of water and total solute absorption, was tested in the normal human jejunum. Jejunal solute and water absorption from saline solutions of the disaccharide maltose was studied by a double-lumen perfusion technique with a proximal occlusive balloon. It was expected that maltose would yield very different results from peptides, but this expectation was not confirmed by this experiment. The assumption that the absorbate is always isotonic with plasma was tested by altering the osmolality of glucose/saline solutions perfused in the jejunal lumen. This assumption was not substantiated by experiment, when the luminal fluid was hypertonic to plasma, so was the absorbate. The findings with peptides and disaccharides may be explained as the production of a hypertonic absorbate by hydrolysis of these solutes to their monomer units. It is therefore concluded that analyses of the relation of net solute and water absorption cannot be used to predict the form in which peptides enter the mucosal cells.

1712 THE NUMBER OF GLYCINE RESIDUES WHICH LIMITS INTACT ABSORPTION OF GLYCINE OLIGOPEPTIDES IN HUMAN JEJUNUM. (Eng.) Adibi, S. A.; Morse, E. L. (Univ. Pittsburgh Sch. Medicine, Pittsburgh, PA 15213). *J. Clin. Invest.* 60(5):1008-1016; 1977.

Studies were carried out in 28 healthy subjects to determine whether glycine peptides of four or more glycine residues can be transported by the peptide carrier system, previously shown to transport diglycine and triglycine. When the jejunum was perfused with tetraglycine solutions, the rate of tetraglycine disappearance increased linearly as the concentration was increased over the range of 12.5-50 mM; however, the rate was slow in comparison to diglycine and triglycine disappearance rates. Glycylleucine, a competitive inhibitor of diglycine and triglycine transport, was without effect on the disappearance rate of tetraglycine, but increased the appearance rates of triglycine and diglycine by over sixfold. These products were the results of hydrolysis of tetraglycine by the brush border enzymes, because the cytosol fraction lacked any hydrolase activity against tetraglycine. When a jejunal ring preparation from Sprague-Dawley rats was incubated with tetraglycine, there was intracellular accumulation of diglycine and triglycine but not of tetraglycine. The rates of glycine uptake were always markedly greater from diglycine and triglycine solutions than from corresponding glycine or tetraglycine solutions; rates of glycine uptake from tetraglycine solutions were either similar to or greater than rates from glycine solutions, depending on the infusion concentration. When the number of glycine residues was increased to hexaglycine, the phenomenon of a greater rate of glycine uptake from a peptide versus a free amino acid solution was no longer apparent. *In vitro* assay of peptide hydrolase activity of the luminal fluid revealed no activity against diglycine and triglycine and only trace activities against tetraglycine, pentaglycine, and hexaglycine. The observations suggest that (a) the disappearance of tetraglycine in the human jejunum is accomplished principally via hydrolysis by brush border oligopeptidases, and (b) the rate limiting step in the uptake of glycine from tetraglycine or higher peptides is due to hydrolysis of these peptides to absorbable products.

1713 IONIC FLUX ACROSS CANINE DUODENUM: MOVEMENT OF BICARBONATE. (Eng.) Himal, H. S.; Rudick, J. (Royal Victoria Hosp., 687 Pine Ave. W., Montreal, Quebec H3A 1A1, Canada). *Am. J. Gastroenterol.* 67(6):574-579; 1977.

The effect of isosmotic biocarbonate-rich solutions on the Brunner's gland area were studied in proximal duodenal explants in eight anesthetized dogs. Volume gain occurred with all instillates and varied indirectly with the concentration of the bicarbonate in the instilled solutions. Net bicarbonate gain occurred with instillate of 40 mEq/l; net insorption occurred with instillates of higher bicarbonate concentration (40-80 mEq/l), the rate of which was dependent on the instillate concentration. Insorption of chloride occurred with the less concentrated bicarbonate solutions (40-80 mEq/l), and enterosorption occurred at higher concentrations (80-120 mEq/l). The modification of intraluminal bicarbonate by the proximal duodenal mucosa is important in the regulation of intraduodenal pH. The abnormal function of this mechanism may play a role in the pathogenesis of duodenal ulceration because of incomplete hydrochloric acid neutralization.

1714 ROLE OF PANCREATIC CHOLESTEROL ESTERASE IN THE UPTAKE AND ESTERIFICATION OF CHOLESTEROL BY ISOLATED INTESTINAL CELLS. (Eng.) Gallo, L. L.; Newbill, T.; Hyun, J.; Vahouny, G. V.; Treadwell, C. R. (George Washington Univ. Sch. Medicine and Health Sciences, Washington, DC 20037). *Proc. Soc. Exp. Biol. Med.* 156(2):277-281; 1977.

To determine if the component in pancreatic juice that is essential for cholesterol absorption is pancreatic cholesterol ester hydrolase (CEH) and to investigate whether cholesterol uptake by the intestinal cell is independent of CEH, isolated intestinal mucosal cells from normal and common duct-cannulated rats were prepared by collagenase dissociation. These cells displayed ultrastructural integrity and retained several metabolic characteristics typical of intact intestinal mucosa. These characteristics included galactose accumulation and its inhibition by dinitrophenol, glucose oxidation, incorporation of labeled leucine into cellular protein, and the uptake and esterification of fatty acid. Cholesterol uptake by cells from common duct-cannulated rats was comparable to that in cells from control animals; however, esterification was only about 25% of that in control cells. Preincubation of the "defective" cells for 30 min with the purified subunit or active form of pancreatic sterol ester hydrolase had no effect on cholesterol uptake but resulted in a fourfold to sixfold increase in the ability of the cells to esterify cholesterol. These studies provide additional evidence for the essential role of pancreatic sterol ester hydrolase in the mucosal esterification of absorbed cholesterol prior to lymphatic transport.

1715 ABSORPTION, PLASMA TRANSPORT, AND CELLULAR RETENTION OF COBALAMIN ANALOGUES IN THE RABBIT: EVIDENCE FOR THE EXISTENCE OF MULTIPLE MECHANISMS THAT PREVENT THE ABSORPTION AND TISSUE DISSEMINATION OF NATURALLY OCCURRING COBALAMIN ANALOGUES. (Eng.) Kolhouse, J. F.; Allen, R. H. (Univ. Colorado

Medical Center, Denver, CO 80220). *J. Clin. Invest.* 60(6):1381-1392; 1977.

Cobalamin (Cbl) analogues containing ^{57}Co and ^{58}Co were synthesized, and their gastrointestinal absorption, plasma transport, and cellular retention in rabbits were compared with those of [^{58}Co]Cbl. Many of the Cbl analogues were bound with low affinity by intrinsic factor, and none of the [^{57}Co]-Cbl analogues were taken up by the ileum or absorbed into the body in amounts comparable to that of [^{58}Co]Cbl. The analogues that were bound by intrinsic factor with high affinity were taken up by the ileum but, in many cases, they were retained there in significant amounts. Most analogues were bound by plasma transcobalamin II with high affinity, and all of these transcobalamin II-[^{57}Co]-Cbl analogue complexes were taken up by a variety of tissues in a manner that was indistinguishable from that of transcobalamin II-[^{58}Co]Cbl. The few analogues that were bound by transcobalamin II with low affinity were taken up by tissues in lesser amounts, and 20-70% of these analogues was rapidly excreted in the urine. All Cbl analogues were bound by the granulocyte R-type Cbl-binding protein with high affinity, and all of the R-type protein-[^{57}Co]-Cbl analogue complexes were cleared rapidly from plasma exclusively by hepatocytes, as occurred with R-type protein-[^{58}Co]Cbl. Some Cbl analogues were released back into the plasma and were disseminated among a variety of tissues via transcobalamin II as occurred with native Cbl. Other Cbl analogues were retained in the liver and eventually excreted in the feces and urine without accumulating in other tissues. These studies indicate that intrinsic factor and the ileum prevent certain Cbl analogues from entering the body and that the granulocyte R-type protein and hepatocytes prevent the dissemination of certain Cbl analogues that may gain entry such as during infections with Cbl analogue-producing bacteria. The fact that transcobalamin II binds and transports a large number of Cbl analogues indicates that these protective mechanisms can be circumvented and supports the feasibility of using Cbl analogues as antimetabolites *in vivo*.

1716 ENERGETICS OF Na^{+}-DEPENDENT SUGAR TRANSPORT BY ISOLATED INTESTINAL CELLS: EVIDENCE FOR A MAJOR ROLE FOR MEMBRANE POTENTIALS.

(Eng.) Kimmich, G. A.; Carter-Su, C.; Randles, J. (Univ. Rochester Medical Center, Rochester, NY 14642). *Am. J. Physiol.* 233(5):E357-E362; 1977.

The mechanics of Na^{+}-dependent sugar transport by isolated intestinal cells were studied. Intestinal epithelial cells isolated from 6-week-old chickens maintained the capability for Na^{+}-dependent concentrative accumulation of 3-*O*-methylglucose (3-OMG). Cells depleted of ATP exhibited a transient accumulation of 3-OMG in response to imposed Na^{+} gradients or when transmembrane ion diffusion potentials (cell interior negative) were established. Phlorizin or lack of extracellular Na^{+} prevented the formation of sugar gradients in every case. A nonconcentrative, non-Na^{+}-dependent sugar transport system was also operative in these cells. The latter system was inhibited to various degrees by phloretin, theophylline, cytochalasin B, and a variety of flavonones and flavones, including apigenin. These agents also inhibited sugar efflux from the cell via this pathway. The concentrative system normally operates against a "leak" of sugar through the nonconcentrative carrier. If the passive system was made inoperative by any of the agents named above, a significant enhancement of steady-state sugar gradients maintained by the cells was observed. With cytochalasin B, gradients as large as 30-fold were established. The energy inherent in cellular Na^{+} gradients could not account for sugar gradients of this magnitude unless both chemical and electrical driving forces were considered. When the passive leak was maximally inhibited, more than half of the total energy required had to be derived from the membrane potential.

1717 UNSTIRRED LAYER AND KINETICS OF ELECTROGENIC GLUCOSE ABSORPTION IN THE HUMAN JEJUNUM IN SITU.

(Eng.) Read, N. W.; Barber, D. C.; Levin, R. J.; Holdsworth, C. D. (Royal Infirmary, Sheffield, England). *Gut* 18(11):865-876; 1977.

Using an electrical technique, the thickness of the unstirred layer in the human jejunum was estimated during kinetic studies of electrogenic glucose absorption to determine whether differences in the thickness of the unstirred layer could explain the low apparent K_m and maximum potential difference (PDmax) for the active electrogenic component of glucose absorption in untreated celiac disease. The unstirred layer in 7 healthy volunteers (632 ± 24 μM) was significantly thicker than in 10 patients with active celiac disease (442 ± 23 μm) but not significantly different in 7 patients who had responded to treatment by gluten withdrawal (585 ± 49 μm). There were similar differences in the values of apparent K_m for electrogenic glucose absorption between healthy controls (36 ± 6 mM), active celiac patients (11 ± 1 mM), and treated celiac patients (31 ± 5 mM). The changes in PDmax, however, showed a different pattern. The PDmax in the active celiac group (6.8 ± 0.7 mV) was lower than in controls (7.6 ± 0.6 mV) but not significantly so, while the PDmax in the treated celiac group (10.6 ± 0.9 mV) was significantly higher than in both the active celiac and control groups. Analysis of the results using a computer simulation indicated that the reduction in apparent K_m in active celiac disease can be caused by the interaction of the decreased maximal absorption rate for glucose with the attenuated unstirred layer. In these circumstances it is not necessary to postulate any change in the affinity of the transport mechanism for glucose ("real K_m").

1718 LACTOSE AND PROTEIN ABSORPTION FROM BREAST MILK AND COW'S MILK PREPARATIONS AND ITS INFLUENCE ON THE INTESTINAL FLORA: INVESTIGATIONS ON TWO INFANTS WITH AN ARTIFICIAL ANUS.

(Eng.) Heine, W.; Zunft, H. J.; Muller-Beuthow, W.; Grutte,

F. K. (Dept. Pediatrics, Wilhelm-Pieck-Univ., 25 Rostock, E. Germany). *Acta Paediatr. Scand.* 66(6): 699-703; 1977.

Lactose and nitrogen balance studies were carried out in two 4-month-old infants with an artificial anus, who were fed either breast milk or a cow's milk preparation, to determine whether the lactose in human breast milk is absorbed less well than the lactose in cow's milk. The concentrations of protein, lactose, glucose, and galactose were measured in the fistula stools, and the fecal bacteria were identified and quantitated. There were relatively high concentrations of lactose and its decomposition products and low concentrations of protein and amino nitrogen in the fistula stools when breast milk was fed. When the cow's milk formula was fed, only traces of lactose but high amounts of protein were present. Higher total intestinal bacteria counts were found in the stools of the infant fed the cow's milk formula. These results support the hypothesis that the lactose from breast milk is not absorbed as well as that in cow's milk. They also indicate that the bacterial flora of the large intestine is influenced by lactose and protein concentrations.

1719 STUDIES OF TRANSLOCATION OF IMMUNOGLOBULINS ACROSS INTESTINAL EPITHELIUM. IV. EVIDENCE FOR BINDING IgA AND IgM TO SECRETORY COMPONENT IN INTESTINAL EPITHELIUM.

(Eng.) Brown, W. R.; Isobe, K.; Nakane, P. K.; Pacini, B. (Veterans Admin. Hosp., 1055 Clermont St., Denver, CO 80220). *Gastroenterology* 73(6):1333-1339; 1977.

Studies were carried out to determine whether secretory component (SC) is a specific receptor on intestinal epithelial cells for IgA and IgM. Initially, frozen sections of human intestinal mucosa were incubated with dimeric monoclonal human IgA_1 conjugated to horseradish peroxidase; adjacent sections were reacted with peroxidase-conjugated antibodies to SC. The conjugated IgA and anti-SC bound to similar sites in the epithelium, that is to basolateral margins and supranuclear cytoplasm of columnar epithelial cells, principally in gland crypts. Binding of the dimeric IgA conjugate was inhibited by pretreating the tissues with unconjugated dimeric IgA or 19S IgM, pretreating the tissues with unconjugated antibodies to SC, or preincubating the dimeric IgA conjugate with free SC. Binding was not inhibited or only partially inhibited by pretreating the tissues with monomeric IgA or IgG, pretreating the tissues with antibodies to human or heterologous immunoglobulins, or preincubating the dimeric IgA conjugate with 11S secretory colostral IgA. The findings indicate that dimeric IgA and 19S IgM are capable of binding *in vitro* to specific sites on intestinal epithelial cells, most likely to SC. This supports the hypothesis that transport of these immunoglobulins into intestinal fluids involves their combination with SC in the epithelium.

1720 ABSORPTION OF HORSERADISH PEROXIDASE BY THE PRINCIPAL CELLS OF THE LARGE INTESTINES OF POSTNATAL DEVELOPING RATS.

(Eng.) Ono, K. (Iwate Medical Univ., Morioka, Japan). *Anat. Embryol.* 151(1):53-62; 1977.

The absorption of horseradish peroxidase in the rat large intestine during postnatal development was investigated by cytochemical and ultrastructural methods. In the ceca and ascending colons from 4-, and 5-day-old rats, intraluminaly injected peroxidase (20 mg/ml) became localized on microvilli, in the intracytoplasmic network of the apical tubules and small vacuoles (tubulo-vacuolar system), in the large supranuclear vacuole, in the Golgi apparatus, on the lateral and basal cell membranes of the surface principal cells, and also in the lumen of blood capillaries in the subjacent propria.
The protein tracer was not seen in the large intestinal epithelial cells that lack tubulo-vacuolar systems and large supranuclear vacuoles within their cytoplasm. In the descending colons of rats of any postnatal age (0-25 days, and adults), the epithelial principal cells were devoid of these membrane systems, and exogenous peroxidase was not detected in the cytoplasm of the principal cells. The results suggest that at least the proximal portion of the large intestine in neonatal animals has the capacity to absorb macromolecular protein through those surface principal cells that have specialized intracellular membrane systems.

1721 LACK OF EFFECT OF VITAMIN D AND ITS METABOLITES ON INTESTINAL PHOSPHATE TRANSPORT IN FAMILIAL HYPOPHOSPHATEMIA OF MICE.

(Eng.) O'Doherty, P. J. A.; DeLuca, H. F.; Eicher, E. M. (Coll. Agricultural and Life Sciences, Univ. Wisconsin, Madison, WI 53706). *Endocrinology* 101(4): 1325-1330; 1977.

Intestinal calcium and phosphate transport was studied in normal and hypophosphatemic mice fed vitamin D-deficient or -supplemented diets, or phosphorus-deficient or -supplemented diets. Regardless of dietary phosphorus levels (low phosphorus, 0.1% or normal phosphorus, 0.3%), the genetic hypophosphatemic mice had drastically reduced levels of serum inorganic phosphate and intestinal phosphate transport while showing only slightly reduced serum calcium and intestinal calcium transport levels. The inclusion of vitamin D (250 ng/day) in the diet did not increase the low serum phosphorus levels and low rates of intestinal phosphate transport in the genetic hypophosphatemic mice, while it did increase serum calcium and intestinal calcium transport levels. The administration of 1,25-dihydroxyvitamin D_3 to the hypophosphatemic mice stimulated intestinal calcium transport but had no effect on intestinal phosphate transport. In contrast, 1,25-dihydroxyvitamin D_3 stimulated both phosphate and calcium transport in the intestine of normal mice. The results support the hypothesis that the primary metabolic disturbance in familial hypophosphatemia involves a defect in phosphate transport mechanisms.

1722 MECHANISM OF INTESTINAL ABSORPTION OF THIAMINE. (Eng.) de Angelis, R. C. (Caixa Postal, 4365, 01000 Sao Paulo, Brazil). *Arq. Gastroenterol.* 14(3):135-143; 1977.

The mechanism of thiamine absorption from the intestinal lumen was studied in mice, hamsters, and rats. *In vitro* experiments were performed using the everted sac technique in the small intestine of mice and hamsters. *In vivo* perfusion of rat small intestine was performed in anesthetized animals. Glucose and the volume of extracellular compartments were also estimated. In *in vitro* studies, when thiamine concentrations in the incubation fluid were up to 0.2 μg/ml, its final concentration in the mucosa was higher than that in the incubation medium. At concentrations above 5 μl/ml, the accumulation of both thiamine and glucose in the mucosa was inhibited by 2-4-dinitrophenol (DNP) or sodium fluoride (NaF) in concentrations over 1×10^{-5} M. At low concentrations (0.05 μg/ml), thiamine entered the epithelial cells by means of active transport mechanism, and the presence of sodium was required. In the presence of metabolic inhibitors (DNP, NaF) or when sodium was replaced by lithium, thiamine passed into the mucosa by diffusion. At thiamine concentrations above 20 μg/ml, its transport was enhanced by DNP, NaF, or anoxia. The rate of transport was inversely related to differences of the potentials generated across the mucosal cells.

1723 EFFECT OF ETHANOL ON INTESTINAL (Na, K) ATPase AND INTESTINAL THIAMINE TRANSPORT IN RATS. (Eng.) Hoyumpa, A. M., Jr.; Nichols, S. G.; Wilson, F. A.; Schenker, S. (Veterans Admin. Hosp., Nashville, TN 37203). *J. Lab. Clin. Med.* 90(6):1086-1095; 1977.

Since previous studies suggested that ethanol may impair thiamine transport by inhibiting serosal (Na, K)-ATPase activity, the effect of ethanol on this enzyme was investigated. (Na, K) ATPase was assayed in the brush border membrane and basolateral membrane (BLM) fractions of rat intestinal mucosal cells. In the jejunum, BLM (Na, K)-ATPase activity was 13-fold greater than in the corresponding brush border preparation. Ethanol (0.5 M), added *in vitro* to the BLM preparation, reduced (Na, K)-ATPase activity in the jejunum to 41% ($p<0.001$) of control. *In vitro* ethanol (0.1 M, 0.2 M, 0.3 M, 0.5 M, 0.7 M, and 1.0 M) decreased jejunal BLM (Na, K)-ATPase activities to 94%, 78%, 58%, 41%, 28%, and 17% of control value (for all but 94%, $p<0.001$), resp. In addition, 1 hr after the p.o. administration of 50, 100, 250, 500, and 750 mg/100 g ethanol, ATPase activity declined to 73%, 52%, 52%, 62%, and 48% of control, resp. (for all, $p<0.01$). The same doses of ethanol decreased the serosal appearance rate of 0.5 μM thiamine to 82%, 48%, 50%, 51%, and 51% of control, resp. (for all but 82%, $p<0.05$). These data clearly show an association between ethanol inhibition of BLM (Na, K) ATPase and decreased thiamine transport, but whether this association is one of cause and effect requires further study.

1724 LIMITED FAT ABSORPTION IN THE LARGE INTESTINE OF MICE: A MORPHOLOGICAL STUDY. (Eng.) Snipes, R. L. (Zentrum fur Anatomie und Zytobiologie der Justus-Liebig-Universitat, Aulweg 123, D-6300 Giessen, W. Germany). *Acta Anat. (Basel* 99(4):435-439; 1977.

Fat absorption and mucosal morphology were studied in the cecum and colon of mice after force-feeding fat and after the injection of predigested donor fat into ligated segments of the large intestine. Both the feeding of corn oil (0.5-1.0 ml for 3 hr at 3 times daily for 2-3 days) and the injection of fat led to the appearance of fat droplets in the epithelial cells of the large intestine; the number of fat droplets in these animals was significantly greater than that in controls. Electron microscopy revealed that large droplets were present in the supra- and infranuclear areas after the exposure to fat. Initial sequestration in the smooth endoplasmic reticulum was not apparent, as it is in the small intestine. After longer absorption times, fat was seen to accumulate in the large intestinal epithelial cells. The accumulation was mostly in the form of increasing droplet size. The observations suggest that the entry of fat into segments of the colon and cecum occurs by simple diffusion. The accumulation of large fat droplets indicates that the ability of the cells to process the fat efficiently for its transport out of the cells is reduced in comparison with that in the proximal small intestine.

1725 ROLE OF BILIARY LECITHIN IN LYMPHATIC TRANSPORT OF FAT. (Eng.) Tso, P.; Balint, J. A.; Simmonds, W. J. (Dept. Physiology, Univ. Western Australia, Nedlands 6009, Western Australia). *Gastroenterology* 73(6):1362-1367; 1977

The role of luminal lecithin in the lymphatic transport of fat as chylomicrons was assessed in male Wistar rats. Two doses of fat (low and high) were fed to control and bile fistula rats. The infusion of a low dose of a mixture of oleic acid and monoolein (35 μmol/hr total fatty acid, molar ratio of 2:1, solubilized in 55 μmol of sodium taur cholate) produced no difference in the lymphatic output of absorbed fat during steady-state (7th and 8th hr) absorption. Infusing a high dose (173 μmol/hr) of a mixture of oleic acid and monoolein produced a lower triglyceride and phospholipid output in bile fistula rats with a higher proportion of oleic acid in lymph lecithin than in control rats. The alterations in bile fistula rats returne to normal following the addition of biliary lecithi (10 μmol/hr) to the infusate. It is concluded that intraluminal biliary lecithin plays a significant role in the translocation of high doses of absorbed fat into lymph and in the amount and type of lecithin synthesized.

1726 ABSORPTION OF PARTIALLY HYDROGENATED SOY OIL BY INFANTS. (Eng.) Klein, G. L.;

MacLean, W. C., Jr.; Lopez de Romana, G.; Massa, E.; Graham, G. G. (615 North Wolfe St., Baltimore, MD 21205). *Nutr. Rep. Int.* 16(4):447-553; 1977.

Apparent absorption of partially hydrogenated soy oil was compared with that of nonhydrogenated soy oil in two groups of infants: five previously malnourished boys, 7-22 months old, and six normal boys, 4-14 months old. Fecal fat excretion while consuming nonhydrogenated soy oil (7.2 ± 2.3 g/day, 14.4 ± 5.5% of intake) was not significantly greater than that while consuming partially hydrogenated soy oil (6.1 ± 2.3 g/day, 12.0 ± 4.6% of intake). Nitrogen balance was similar with both diets. There seems to be no contraindication to the use of the more stable partially hydrogenated form of the oil in formulas intended for infants over 4 months old; however, these studies do not include infants in the immediate neonatal period.

1727 PHARMACEUTICAL APPROACH TO THE ORAL DOSAGE FORM OF MACROMOLECULES: EFFECT OF BILE SALTS AND OIL-IN-WATER EMULSIONS ON THE INTESTINAL ABSORPTION OF UROGASTRONE IN THE RAT. (Eng.) Hori, R.; Okumura, K.; Inui, K. I.; Nakamura, N.; Miyoshi, A.; Suyama, T. (Hiroshima Univ. Sch. Medicine, Hiroshima, Japan). *Chem. Pharm. Bull. (Tokyo)* 25(8):1974-1979; 1977.

The absorption of urogastrone, a glycoprotein with gastric antisecretory activity, from the rat intestine was studied using a technique in which the indirect assay of its appearance in the blood stream was facilitated by a concomitant lowering of gastric acid secretion. The i.v. or i.p. administration of urogastrone (0.3-0.5 mg, i.v.; 1.3-2.5 mg, i.p.) produced 40% inhibition of control levels of H^+ output. The intrajejunal administration of urogastrone (15.0-20.0 mg) produced only a slight inhibitory response. However, when urogastrone was administered intrajejunally with various bile salts or oil-in-water emulsions, a strong inhibitory response of gastric H^+ secretion was elicited. Trioctanoin emulsion was the most effective, followed by olive oil, diethyl phthalate, and liquid paraffin, resp. The results suggest that orally active dosage forms for poorly absorbable macromolecules such as urogastrone might be prepared by pharmaceutical modification.

1728 EFFECTS OF CHOLERA ENTEROTOXIN ON INTESTINAL TISSUE WATER AS MEASURED BY NUCLEAR MAGNETIC RESONANCE (NMR) SPECTROSCOPY: II. (Eng.) Udall, J. N.; Alvarez, L. A.; Chang, D. C.; Soriano, H.; Nichols, B. L.; Hazlewood, C. F. (Baylor Coll. Medicine, Houston, TX 77030). *Physiol. Chem. Phys.* 9(1):13-20; 1977.

To determine the effects of cholera enterotoxin on intestinal tissue water, an open-ended loop experiment was performed in male rats. A double ligature was placed 20 cm proximal to the cecum, and 2-4 cm^3 of saline was injected distal to the ligature. A temporary ligature was placed proximal to the cecum, and 2.0 ml of enterotoxin was injected into the closed loop. A control was injected with 2.0 ml saline. In addition, the intestinal villi were scraped, centrifuged at 2,000 revolutions per min for 10 min, and the villous specimens were evaluated for water concentration and nuclear magnetic resonance (NMR) relaxation parameters. The average luminal fluid volume for the enterotoxin-exposed animal was 1.3 ml, compared to 0.3 ml for the control ($p<0.01$). Water percentage in intestinal tissue was 80.1 ± 0.5% for the toxin-exposed and 81.9 ± 0.3% for the control ($p<0.005$). In the scraped villi experiment, the percentage of water, corrected for fat, was 80.9 ± 0.1% in the control, and 86.9 ± 0.6% in the toxin-exposed animal ($p<0.01$). The NMR relaxation times of water protons were significantly lengthened in all toxin-exposed tissue. The results confirm the hypothesis that enterotoxin increases intestinal cell water content by acting on the mucosal cells.

MOTILITY

1744 MANOMETRIC STUDIES OF THE UPPER ESOPHAGEAL SPHINCTER. (Eng.) Berlin, B. P.; Tedesco, F.; Fierstein, J. T.; Ogura, J. H. (Washington Univ. Medical Sch., 517 S. Euclid, St. Louis, MO 63110). *Ann. Otol. Rhinol. Laryngol.* 86(5, Part 1):598-602; 1977.

A modification of a multiluminal catheter was used to study the pharyngoesophageal sphincter (PES) in 6 normal patients and in 13 patients who had undergone partial laryngeal surgery. Manometry is carried out with a six-lumen catheter where lateral orifices are spaced at 60-degree intervals around the circumference of the catheter at the same level. The backbone of this catheter is a length of polyvinyl tubing with an outside diameter of 6 mm. Six pieces of 1.5-mm tubing are fused around the internal circumference of the tube. Pressure profiles in the normal patients revealed a marked increase in intraluminal pressure in the anterior-posterior direction; this increase is explained by the anatomy of the cricopharyngeal muscle, which does not insert in a median raphe. These readings were reliable and reproducible. The operative patients included nine subtotal supraglottic laryngectomies and four partial laryngopharyngectomies. Eight patients had a cricopharyngeal myotomy and five did not. Pre- and postoperative measurements in this series revealed a marked decrease in PES pressure in those patients who had a myotomy; however, all patients were decannulated and swallowed postoperatively without clinical evidence of aspiration. All future manometric studies of the PES should employ a multilumined catheter so that the differential pressures in the upper esophagus are recorded.

1745 STATIC AND DYNAMIC CHARACTERISTICS OF FLUID-FILLED ESOPHAGEAL MANOMETRY SYSTEMS. (Eng.) Ask, P.; Oberg, P. A.; Tibbling, L. (Dept. Medical Engineering, Linkoping Univ., S-581 85 Linkoping, Sweden). *Am. J. Physiol.* 233(5):E389-E396; 1977.

Esophageal manometric systems with water-filled catheters were characterized using model experiments. The examined parameters were catheter dimension, catheter compliance, catheter resistance, pump type, pump compliance, and perfusion flow. Accurate static pressure measurements were obtained for perfused systems independently of the parameters investigated. The dynamic characteristics varied with catheter diameter and perfusion flow. For catheters with low diameter, a narrow band width was obtained for the investigated perfusion flows. The results are expressed in terms of an electric model of the measurement system. Perfusion pumps with low compliance are recommended to improve the dynamic properties of the measurement system.

1746 ESOPHAGEAL MANOMETRY IN THE OPOSSUM. (Eng.) Schulze, K.; Dodds, W. J.; Christensen, J.; Wood, J. D. (Univ. Iowa Coll. Medicine, Iowa City, IA 52242). *Am. J. Physiol.* 233(3): E152-E159; 1977.

Esophageal manometry was carried out in normal opossums to provide basal data about normal esophageal motor functions *in vivo*. At rest, separate and distinct high pressure zones were recorded at the level of the lower esophageal sphincter, diaphragmatic hiatus, aortic arch, and upper esophageal sphincter. Each zone demonstrated a characteristic pattern of pressures in the radii of the coronal section and a characteristic response to swallowing. Pressures in the sphincters fell with swallowing. Peristalsis was not bolus-dependent and occurred with 98% of swallows. Pressures generated by peristalsis were greater in the middle of the esophagus than at the ends. Values for resting lower esophageal sphincter pressure and the characteristics of peristalsis were reproducible between different studies in the same animals.

1747 LOWER SPHINCTER OF THE OPOSSUM ESOPHAGUS IN PSEUDOPREGNANCY. (Eng.) Schulze, K.; Christensen, J. (Univ. Hosp., Iowa City, IA 52242). *Gastroenterology* 73(5):1082-1085; 1977.

The possible role of estrogen and progesterone in the development of changes in esophageal function during pregnancy was studied by producing hormone-induced pseudopregnancy in opossums. The animals received estradiol valerate (100 μg/day, i.m.) from day 1 to day 12 and medroxyprogesterone acetate (15 mg) from day 7 to day 12. Controls received no injections. Both groups underwent manometry on days 1, 7, and 12. Lower esophageal sphincter pressure decreased ($p<0.05$) in treated animals from 58 ± 13 mm Hg and 57 ± 11 on days 1 and 7, resp., to 44 ± 10 mm Hg on day 12. The lower esophageal sphincter pressure remained unchanged in controls. In both groups, there was no change in peristaltic wave pressure, duration, or velocity in the distal 6 cm of the esophagus. No abnormal peristaltic phenomena were observed. Esophageal muscle strips prepared from treated animals showed responses to electrical field stimulation of intrinsic nerves that were like those from control animals. The same was true for responses to acetylcholine and pentagastrin. Total tissue water and total tissue potassium content did not differ in treated and control animals. The fact that the lower esophageal sphincter is situated well below the diaphragmatic hiatus in the opossum, making the pressures produced by these two structures clearly differentiated on manometry, indicates that the effect of estradiol and progesterone on the lower esophageal sphincter pressure is not attributable to changes at the diaphragmatic hiatus.

1748 LOWER-ESOPHAGEAL SPHINCTER FUNCTION DOES NOT DETERMINE RESTING UPPER-ESOPHAGEAL SPHINCTER PRESSURE. (Eng.) Berte, L. E.; Winans, C. S. (Univ. Chicago Pritzker Sch. Medicine, Chicago, IL). *Am. J. Dig. Dis.* 22(10):877-880; 1977.

Records of 269 esophageal motility studies of patients without prior gastroesophageal surgery, achalasia, scleroderma, gastroesophageal malignancy, or peptic esophageal strictures were reviewed to determine the relationship between lower esophageal sphincter (LES) function and upper esophageal sphincter (UES) pressure. Average and greatest UES pressures were similar in patients with LES pressures less than 10 mm Hg or greater than 20 mm Hg, and in patients with and without gastroesophageal reflux as determined by an intraesophageal pH electrode test. The belief that patients with weak lower esophageal sphincters and gastroesophageal reflux have stronger upper esophageal sphincters to guard against pharyngeal reflux and aspiration cannot be confirmed by current manometric techniques.

1749 MYOGENIC AND NEURAL CONTROL SYSTEMS FOR ESOPHAGEAL MOTILITY. (Eng.) Sarna, S. K.; Daniel, E. E.; Waterfall, W. E. (McMaster Univ. Medical Center, 4W8, 1200 Main St. West, Hamilton, Ontario L8S 4J9, Canada). *Gastroenterology* 73(6): 1345-1352; 1977.

The role of myogenic and neural control systems in esophageal motility was studied in anesthetized opossums by applying electrical pulses at 20 to 40 V and 100- to 400-msec pulse width directly to muscle layers, by cervical vagal stimulation (10-25 pulses/sec, 0.5- to 5-msec pulse width, 10-40 V), and by balloon distention. Direct muscle stimulation resulted in a propagated contraction in 13 of 22 opossums (proximal propagation from a distal stimulation site and vice versa). The velocity of propagation was of the same order of magnitude as that of a spontaneous swallow (<5 cm/sec). The propagated contractions were not blocked by i.v. or close intra-arterial (i.a.) atropine (100-500 μg/kg, i.v.; 100-400 μg/kg, i.a.), hexamethonium (5-10 mg/kg, i.v.; 10 mg, i.a.), or by intra-arterial tetrodotoxin (20 μg). Smooth muscle depolarization by i.a. 40 mM KCl or tetraethylammonium (10 mg) brought about propagated contractions in those opossums that did not show this in the first place. Generally, these propagated contractions could also be initiated in these opossums by applying 2 to 3 stimulating pulses 1 to 1.5 sec apart. The propagated contractions in response to direct muscle stimulation were observed in all opossums 2 to 20 min after death. Cessation of vagal stimulation and balloon relaxation produced "off-responses" that were blocked by tetrodotoxin. The propagation of off-responses was much faster than the swallow-induced peristaltic contractions. The myogenic control system in the esophagus is capable of producing propagated contractions independently, which resemble normal esophageal peristalsis in propagation velocity and may be the underlying system responsible for it. This system may, however, be modulated by the extrinsic and intrinsic nerves.

1750 AGE-RELATED CHANGES IN FORCE, STRESS, AND PRESSURE OF LOWER ESOPHAGEAL SPHINCTER OF THE RAT.

(Eng.) Biancani, P.; Behar, J.; Zabinski, M. P. (Dept. Internal Medicine, Yale Univ., New Haven, CT 06510). *Am. J. Physiol.* 233(5):E407-E415; 1977.

Age-related changes in the mechanical characteristics and changes in the dimensions of the lower esophageal sphincter (LES) were investigated in Sprague-Dawley rats. Transversely cut lower esophageal sphincter rings of 3-week-, 6-week-, 3-month-, and 1-yr-old rats were studied *in vitro* at 80 cycles/sec stimulation (50 mA, 2 msec). *In vivo* length (circumference) and thickness of the circular muscle layer was found to increase with age. The length at which the muscle exerted maximum active force during electrical stimulation occurred for all age groups at approximately three times the *in vivo* length. When compared with adjacent sections, the sphincter exerted the highest active force and stress, both at the *in vivo* length and at the length of maximum active force. A large increase in the active force was observed in rats between 3 and 6 weeks, followed by a small decrease in the 1-yr-old rats. The active stress remained nearly constant between the ages of 3 weeks and 3 months and decreased thereafter. The large increase in active force observed between 3 and 6 weeks was caused by a slight increase in muscle contractility as well as by a more than threefold increase in the amount of circular muscle present. In rats older than 6 weeks, however, the active contractile force fell slightly, in spite of increased muscle mass, due to a substantial decrease in muscle contractility. Pressure-diameter relationships calculated from the *in vitro* force-length data and compared with previously determined *in vivo* pressure-diameter data, demonstrate good correlation between the *in vivo* and *in vitro* data.

1751 EFFECT OF CIGARETTE SMOKING ON THE LOWER OESOPHAGEAL SPHINCTER: ASSESSMENT OF NORMAL AND SYMPTOMATIC PATIENTS USING THE RAPID PULL-THROUGH TECHNIQUE OF OESOPHAGEAL MANOMETRY.

(Eng.) Chattopadhyay, D. K.; Greaney, M. G.; Irvin, T. T. (Royal Infirmary, Sheffield, England). *Gut* 18(10): 833-835; 1977.

A rapid pull-through technique of manometry was used to determine the effect of cigarette smoking on lower esophageal sphincter pressure (LESP) in 10 asymptomatic volunteers and in 10 patients with gastroesophageal reflux. Basal LESP measurements in the two groups were not significantly different, but LESP was reduced by 19% in asymptomatic subjects ($p<0.01$) and by 21% in symptomatic patients ($p<0.02$) during cigarette smoking. The results suggest that smoking should be avoided in the clinical management of gastroesophageal reflux.

1752 INTESTINAL MYOELECTRIC ACTIVITY AFTER ACTIVATION OF CENTRAL EMETIC MECHANISM.

(Eng.) Stewart, J. J.; Burks, T. F.; Weisbrodt, N. W. (Texas Medical Center, Houston, TX 77030). *Am. J. Physiol.* 233(3):E131-E137; 1977.

Changes in intestinal myoelectric activity after the intraventricular or peripheral injection of emetic drugs were studied in cats. Morphine (200 µg), apomorphine (200 µg), or epinephrine (150 µg) were injected either into a lateral cerebral ventricle or i.p. in cats implanted with monopolar, extracellular electrodes along the entire small intestine. Intraventricular injection of the agents produced emesis in a number of animals tested (4/10, 4/11, and 8/11 with morphine, apomorphine, and epinephrine, resp.). Each episode of retching and vomiting was preceded by a characteristic intestinal myoelectric pattern that consisted of the following: a dampening in slow-wave amplitude, followed by an intense burst of spike potentials that lasted several seconds. The pattern was recorded first in the distal small intestine, then migrated orad at a velocity of 2-3 cm/sec. After emesis, slow-wave frequency was reduced at recording sites along the entire small intestine. Atropine (100 µg/kg, i.p.) did not affect the emetic potency of epinephrine but abolished both the orally migrating spike-burst complex and the reduction in slow-wave frequency associated with vomiting. Naloxone (200 µg, intraventricularly) abolished morphine- and apomorphine-induced emesis without affecting the emetic potency of epinephrine; phentolamine (200 µg, intraventricularly) antagonized the emetic action of epinephrine without diminishing the emetic potency of morphine. No emesis, intestinal spike-burst complex, or changes in slow-wave frequency occurred after the i.p. administration of the emetic agents at the same doses effective centrally. Activation of the central emetic mechanism is associated with a myoelectric pattern recorded from the small intestine indicative of a reverse peristaltic wave.

1753 MIGRATING MYOELECTRICAL COMPLEX OF THE SMALL INTESTINE: AN INTRINSIC ACTIVITY MEDIATED BY THE VAGUS.

(Eng.) Ruckebusch, Y.; Bueno, L. (Ecole Nationale Veterinaire, 31076 Toulouse Cedex, France). *Gastroenterology* 73(6):1309-1314; 1977.

The relative influence of neural versus hormonal components on the migrating myoelectrical complex (MMC) pattern and its disruption by feeding was studied in dogs. In healthy, conscious parenterally fed dogs and in sheep fed their usual diet, the MMC comprised two distinct phases termed irregular and regular spiking activity and was followed by a period of quiescence. The pattern persisted after bilateral transthoracic vagotomy and in animals with alloxan-induced diabetes. In dogs, feeding disrupted the MMC pattern by obliterating the phases of regular spiking activity and quiescence for 6 to 12 hr, depending upon the amount of dry matter intake. After vagotomy, a latency in the disruption of the migrating myoelectrical complex pattern with feeding occurred and in vagotomized, diabetic dogs, the duration of disruption was strongly reduced. In sheep, the duration of irregular spiking activity of a jejunal segment increased or decreased corresponding to the bulk of digesta, a phenomenon damped after vagotomy. The results indicate that the role of the vagus is limited to (a) prompting prandial disruption, which is then maintained by hormonal effect; and (b) regulating the irregular spiking activity duration in relation to the bulk of digesta.

1754 THE GASTROINTESTINAL MYOELECTRIC RESPONSE TO 13-Nle-MOTILIN INFUSION DURING INTERDIGESTIVE AND DIGESTIVE STATES IN THE CONSCIOUS DOG.

(Eng.) Wingate, D. L.; Ruppin, H.; Thompson, H. H.; Green, W. E. R.; Domschke, W.; Wunsch, E.; *et al.* (London Hosp. Medical Coll., Whitechapel, London E1 1BB, England). *Acta Hepatogastroenterol.* 24(4):278-287; 1977.

To determine whether 13-norleucine motilin (13-nle-motilin) enhances small intestinal electrical spike activity in conscious dogs under physiological conditions, as it does in the isolated preparation, intestinal myoelectric activity was studied in three fasted dogs with electrodes surgically implanted in the stomach and small intestine, during separate and combined i.v. infusions of 13-nle-motilin and pentagastrin (PG). Basal recordings confirmed the presence of regular interdigestive myoelectric complexes (MCs). In doses under 50 ng/kg/hr, 13-nle-motilin was without effect; higher doses (up to 400 ng/kg/hr) resulted in the interpolation of one or more MCs in the spontaneous sequence. The rate of aboral transit of 13-nle-motilin-induced MCs did not differ significantly from that of spontaneous MCs. When MCs were abolished by feeding or PG infusion, simultaneous 13-nle-motilin administration was without effect on spike activity, but slightly attenuated the accelerating effect of gastrin on the gastric pacemaker frequency. The myoelectric events triggered by 13-nle-motilin suggest that in the conscious dog the polypeptide may not act directly on the smooth muscle cell, as it does *in vitro*, but through an extra-enteric neural control mechanism that is uncoupled by gastrin.

1755 THE CONTRIBUTION OF PROSTAGLANDINS IN THE MUSCLE OF HUMAN ISOLATED SMALL INTESTINE TO NEUROGENIC RESPONSES.

(Eng.) Bennett, A.; Stockley, H. L. (King's Coll. Hosp. Medical Sch., Denmark Hill, London SE5 8RX, England). *Br. J. Pharmacol.* 61(4):573-578; 1977.

The contribution of prostaglandins to neurogenic responses in the longitudinal and circular muscle was studied in the human ileum. In strips cut parallel to the longitudinal or circular muscle, indomethacin (2-10 μg/ml) usually lowered the tone, thus probably accounting for the reduction of nerve-mediated relaxations to electrical field stimulation. In longitudinal muscle strips, indomethacin enhanced contractions that occurred during electrical stimulation, probably because tone fell, but antagonized after-contractions. In the circular muscle, indomethacin reduced initial contractions but enhanced after-contractions. Prostaglandin E_2 (100 ng/ml) counteracted all of the effects of indomethacin in the longitudinal muscle and most of those in the circular muscle; prostaglandin F_{2_α} (100 ng/ml) restored circular muscle tone. The results suggest that prostaglandins affect the muscle directly and contribute to the regulation of tone. They may also mediate noncholinergic contraction in longitudinal muscle and suppress contractility in the circular muscle.

1756 CORRELATION OF VARIATIONS IN INTRALUMINAL PRESSURE AND POTENTIAL DIFFERENCES IN THE PERFUSED COLON.

(Eng.) Postaire, J. G.; Gerard, J.; Devroede, G.; Van Houtte, N. V. (Departement du Genie Electrique, Universite de Sherbrooke, Sherbrooke, Quebec, Canada). *Gut* 18(10):771-778; 1977.

To investigate the nature of variations in the large intestinal potential differences, a continuous perfusion of isotonic saline was carried out in the colon of 14 rats. Intraluminal pressure and potential differences between the lumen and the peritoneal cavity were continuously and simultaneously recorded, while impedance of the system and respiration were also constantly monitored. To obtain a quantitative evaluation of the data, Fast Fourier Transform was performed on the signals and their derivatives, which were auto- and cross-correlated. While there was no obvious relation between pressure and potential in the unperfused colon, there was clear visual qualitative evidence that, during steady-state conditions of perfusion, an increase in intraluminal pressure was accompanied by a decrease in potential differences, while impedance of the recording system remained unchanged. Computer analysis disclosed four narrow ranges of stable frequencies for both pressure and potential. They were centered around 0.3, 1.75, 10.7, and 75 cycles/min, the latter being synchronous with respiration. It is concluded that the variations of potential differences recorded during perfusion are not electrical artifacts; the fast rhythm is probably induced by respiration, which increases intracolonic pressure and that, in turn, reduces the absolute value of potential differences, which remain negative mucosa *versus* serosa. The slower rhythms are synchronous for pressure and potential.

1757 HUMAN COLONIC MYOELECTRIC ACTIVITY IN RESPONSE TO PROSTIGMIN AND THE GASTROINTESTINAL HORMONES.

(Eng.) Snape, W. J., Jr.; Carlson, G. M.; Cohen, S. (Hosp. Univ. Pennsylvania, 3400 Spruce St., Philadelphia, PA 19104). *Am. J. Dig. Dis.* 22(10):881-887; 1977.

Colonic myoelectric activity was determined using a mucosal clip electrode in 12 normal subjects and in cats, both in the basal state and following the administration of prostigmin, pentagastrin, cholecystokinin, or secretin. Slow-wave activity was present 49 ± 3.0% of the recording time in man and occurred at two frequencies, 6.5 ± 0.1 cycles/min and 3.5 ± 0.1 cycles/min, in the rectum. Spike potentials were infrequent in the basal state. Prostigmin (1.0 mg, i.m.), pentagastrin (0.5 μg/kg, i.v.), or cholecystokinin (1.0 U/kg) did not affect the slow-wave activity or frequency, but these agents significantly increased the number of spike potentials ($p<0.05$). Secretin had no effect on myoelectric activity. The electrode system was tested in the cat and showed excellent correlation of the myoelectric activity between the mucosal clip electrode and a serosal electrode. These studies indicate that a mucosal clip electrode provides an accurate method of recording colonic myoelectric activity when compared to a serosal electrode in the cat. In man, slow-wave activity is present only intermittently and exists at two frequencies. Gastrointestinal hormones and prostigmin increase spike potential discharge without altering slow-wave activity or frequency.

1758 EFFECT OF CAPSAICIN ON ELECTRICAL SLOW WAVES IN THE ISOLATED CAT COLON.

(Eng.) Anuras, S.; Christensen, J.; Templeman, D. (Dept. Internal Medicine, Univ. Iowa, Iowa City, IA 52242). *Gut* 18(8):666-669; 1977.

To determine whether the laxative effect of capsaicin involves an alteration of electrical slow waves of the colon, the effect of that agent on the electromyogram of the isolated cat colon was examined. At a concentration of 10^{-4} M, it caused a significant reduction in the frequency of the electrical slow waves in the proximal half of the colon. The frequency fell to its lowest value, 45% of control ($p<0.001$), in the most proximal 10% of the organ below the ileocecal junction, and the effect progressively diminished along the colon. In the distal half of the colon, the change in frequency was not significant. Sectioning of the colon into segments reduced the frequency of the slow waves in the proximal half of the colon, and capsaicin further reduced the frequency in the segments representing the proximal 30% of the colon. The results suggest that the capsaicin effect is an uncoupling of slow wave oscillators.

1759 EFFECTS OF GLUCAGON AND SECRETIN ON FOOD- OR MORPHINE-INDUCED MOTOR ACTIVITY OF THE DISTAL COLON, RECTUM, AND ANAL SPHINCTER.

(Eng.) Chowdhury, A. R.; Lorber, S. H. (777 Court St., Reading, PA 19601). *Am. J. Dig. Dis.* 22(9):775-780; 1977.

The effects of glucagon and secretin on food- or morphine-induced motor activity of the distal colon, rectum, and internal anal sphincter were investigated in 12 healthy subjects. Intraluminal pressure changes were measured using a triple-lumen polyvinyl tube assembly with three side orifices. Glucagon (3 μg/kg over 30 sec, followed by a continuous infusion of 30 μg/kg/hr, i.v.) caused significant inhibition of food- or morphine (0.1 mg/kg, i.v.)-induced motor activity of both the distal colon and rectum. In contrast, secretin (0.5 U/kg over 30 sec, followed by 2 U/kg/hr, i.v.) did not suppress morphine-induced motor activity but did significantly inhibit food-stimulated motor activity of the distal colon. The inhibitory effect of secretin on motor activity of the rectum was insignificant. Morphine, but not food, elevated the pressure of the anal sphincter, which was not affected by glucagon or secretin. Hyperglycemia, produced by the infusion of 5% glucose, had no effect on motor activity. These studies demonstrate that glucagon but not secretin, in the doses employed, inhibits morphine-induced motor wave activity of both the distal colon and rectum and that this inhibitory effect is not secondary to hyperglycemia. Furthermore, the rise in anal sphincter pressure is not affected by glucagon or secretin.

1760 STUDY OF GASTRIC EMPTYING USING A FERROMAGNETIC TRACER.

(Eng.) Benmair, Y.; Dreyfuss, F.; Fischel, B.; Frei, E. H.; Gilat, T. (Weizmann Inst. Science, Rehovot, Israel). *Gastroenterology* 73(5):1041-1045; 1977.

A new ferromagnetic method for the measurement of gastric emptying is described, and the results of gastric emptying studies in 61 subjects with normal gastric motility are presented. An inert tracer, magnesium ferrite, is added to a test meal. Its amount in the stomach is then measured at regular intervals by an external transducer using its ferromagnetic properties. The method is noninvasive and devoid of radiation exposure. The magnetic fields used are harmless. The shape of the gastric emptying curve obtained in the 61 subjects conformed best to an exponential function. The mean half-time of gastric emptying was 49 ± 17.4 min. In this limited series, age and sex did not affect gastric emptying. In 14 of 15 cases, there was a good correlation between the results of this method in determining the end point of gastric emptying and those of an x-ray method. This ferromagnetic method appears to be uncomplicated, inexpensive, reliable, and reproducible.

1761 CANINE GASTRIC EMPTYING OF SOLIDS AND LIQUIDS.

(Eng.) Hinder, R. A.; Kelley, K. A. (Mayo Medical Sch., Rochester, MN 55901). *Am. J. Physiol.* 233(4):E335-E340; 1977.

To test the hypothesis that liquids are emptied from the stomach, whereas solids are retained for reduction to a size suitable for passage into the duodenum, gastric emptying of labeled solids and a liquid was simultaneously assessed by quantitating the rate of appearance of the gastric markers in the duodenum. Four dogs received a digestible solid (50 g of liver tagged with $[^{57}Co]$cyanocobalamine and diced into 1-cm cubes), an indigestible solid (40 radiopaque plastic spheres, diameter 7 mm), and a liquid (400 ml of either 1% or 10% dextrose tagged with polyethylene-[1,2-^{3}H]glycol). The rate of gastric emptying of cubed liver was similar whether the liver was given alone or with solutions of the rapidly emptying 1% dextrose, but its rate of emptying was slowed by the slower emptying 10% dextrose. Homogenization of the liver speeded its emptying. Moreover, the homogenized liver emptied even faster when dispersed in 1% dextrose and emptied more slowly when dispersed in 10% dextrose, but in both instances the liver emptied at the same rate as the solution with which it was mixed. Indigestible spheres were nearly all retained, whereas the liver and the dextrose were emptied. It appears that the stomach empties liquids and retains solids for reduction to a smaller size, after which they are discharged at the same rate as the liquid then present in the stomach.

1762 GASTRIC EMPTYING OF WHOLEMEAL AND WHITE BREAD. (Eng.) Grimes, D. S.; Goddard, J. (Withington Hosp., Manchester M20 8LR, England). *Gut* 18(9):725-729; 1977.

The rates at which solid and liquid leave the stomach after meals of whole-meal and white bread were studied in 11 normal subjects (9 men, 2 women) and in rats, using a double isotope technique. There was no difference in the rates at which the solid phases of the gastric contents left the stomach, but liquid left the stomach significantly more rapidly with white bread than with whole-meal bread ($p<0.005$). Furthermore, the amount of liquid leaving the stomach unaccompanied and therefore unbuffered by solid was significantly greater after white bread than whole-meal bread. These findings may be of significance in the pathogenesis of duodenal ulcer, and it is suggested that the substitution of whole-meal bread for white bread might be of benefit to patients with duodenal ulcer and nonulcer dyspepsia.

1763 MYOELECTRICAL AND MECHANICAL ACTIVITY DURING THE EMPTYING OF LIQUID TEST MEALS FROM THE ISOLATED CANINE STOMACH. (Eng.) Kowalewski, K.; Kolodej, A. (Surgical-Medical Res. Inst., Univ. Alberta, T6G 2N8 Edmonton, Alberta, Canada). *Rend. Gastroenterol.* 9(2):122-126; 1977.

The effect of liquid meals on gastric emptying, antral electrical activity, and antral mechanical activity was studied in 14 isolated canine stomachs, perfused *ex vivo* with homologous blood. The following liquid meals were used: normal saline, 50 mM HCl, 30% glucose, 80 mM sodium oleate, and 15% liver extract. The emptying of acid meal and of liver extract was slower than the emptying of the other meals. The frequency of electrical control activity (ECA) was significantly decreased after the acid meal (4.6 ± 0.4 ECA/min) and increased after liver extract (6.0 ± 0.2 ECA/min), as compared with the effect of other meals on ECA. The force and frequency of antral contractions increased after the liver extract meal, and was low after the acid meal, confirming the results of previous *in vivo* studies on humans and dogs.

1764 EFFECTS OF GASTROINTESTINAL HORMONES ON THE ELECTRICAL AND MECHANICAL ACTIVITY OF THE CAT STOMACH. (Eng.) Ohkawa, H.; Watanabe, M. (Yamaguchi Univ. Sch. Medicine, Ube 755, Japan). *Tohoku J. Exp. Med.* 122(3):287-298; 1977.

The effects of gastrointestinal hormones on electrical and mechanical activity of smooth muscle of the cat stomach were studied. Spontaneous electrical activity of antrum preparations consisted of slow waves with superimposed spike-like potentials. Phasic contractions occurred synchronously with the electrical activity. Pentagastrin (1.25×10^{-7}-2.5×10^{-7} g/ml), tetragastrin (1.25×10^{-7} g/ml), pancreozymin (0.05-0.1 U/ml), and secretin (0.05-0.25 U/ml) increased the frequency of slow wave component and the amplitude of phasic contraction. Atropine (2.5×10^{-6} g/ml) and tetrodotoxin (1.6×10^{-7} g/ml) did not block the spike-like potential and slow wave component. Norepinephrine (5×10^{-6} g/ml) and verapamil (3×10^{-6}-1×10^{-5} g/ml) blocked the phasic contraction. The excitatory effects of these gastrointestinal hormones were observed in the presence of atropine, tetrodotoxin, and dibenamine, but not with verapamil. When the mechanical activity of the antral strips was depressed by caffeine or theophylline, the excitatory effects of gastrointestinal hormones were also suppressed. The excitatory effects produced by these hormones were potentiated by imidazole. These results suggest that gastrointestinal hormones have a direct excitatory action on the longitudinal smooth muscle of the antrum and that the excitatory action is associated with phosphodiesterase activity and intracellular cyclic AMP content.

1765 EFFECT OF SYNTHETIC MOTILIN ON GASTRIC MOTOR ACTIVITY IN CONSCIOUS DOGS. (Eng.) Itoh, Z.; Takeuchi, S.; Aizawa, I.; Takayanagi, R. (Gunma Univ. Sch. Medicine, Maebashi 371, Japan). *Am. J. Dig. Dis.* 22(9):813-819; 1977.

The effect of the i.v. infusion of synthetic motilin on gastric motor activity was investigated by means of chronically implanted force transducers in four conscious dogs. Since the gastric motor pattern was found to consist of two major subpatterns during a 24-hr period, i.e., digestive and interdigestive motor activity, motilin was tested for its motor stimulating activity in both states. The digestive pattern was characterized by steady, low-amplitude antral contraction, while the interdigestive pattern consisted of a series of high-amplitude contractions in both the gastric body and antrum, with intervening and long-lasting motor quiescence. Motilin had no influence upon gastric motor activity in the digestive state. However, during the interdigestive state, motilin (0.3-2.7 μg/kg/hr) induced motor activity similar to the naturally-occurring interdigestive contractions in a dose-related fashion. Since motilin is released by duodenal alkalinization in the dog, it is postulated that motilin is a substance to control the interdigestive contractions in the dog, although other reports describe motilin release by duodenal acidification and inhibition of gastric emptying in man. Endogenous stimuli leading to motilin release may be different among species. This study indicates that motilin induces a contractile pattern similar to that seen during the interdigestive state in conscious dogs.

1766 MOTILIN ENHANCES GASTRIC EMPTYING OF LIQUIDS IN DOGS.

(Eng.) Debas, H. T.; Yamagishi, T.; Dryburgh, J. R. (Dept. Surgery, Univ. British Columbia, 700 W. 10th Ave., Vancouver, British Columbia V5Z 1L5, Canada). *Gastroenterology* 73(4, Part 1):777-780; 1977.

The effect of natural motilin on gastric emptying of liquids was studied in dogs before and after either truncal vagotomy or antrectomy or both. The rate of gastric emptying was determined in six dogs with gastric fistulae by measuring the volume of fluid remaining in the stomach 10 min after instillation of 300 ml of 0.15 M NaCl containing phenol red (60 mg/l) as marker. The rate of emptying was determined with the dogs receiving only saline (controls) and while different doses of motilin were infused i.v. The rate of emptying of a solid meal was studied by measuring the amount of solid material (weight after desiccation) left in the stomach 15, 30, 60, 90, and 120 min after a meal of proprietary dog food equivalent in dry weight to 3 g/kg of body weight. Motilin was found to be a potent accelerator of gastric emptying of liquids but not of solids. The antrum was not needed for this action. Vagotomy shifted the dose-response curve to the right, increasing the half-dose 10-fold. These findings suggest that motilin acts on the proximal stomach to enhance emptying and that its potency depends on the presence of vagal tone. They also support the hypothesis that the proximal stomach mainly controls the emptying of liquids.

1767 EFFECTS OF VAGOTOMY ON THE ULTRASTRUCTURE OF THE NERVES OF DOG STOMACH.

(Eng.) Oki, M.; Daniel, E. E. (McMaster Univ. Medical Center, Hamilton, Ontario L8S 4J9, Canada). *Gastroenterology* 73(5):1029-1040; 1977.

The effects of vagotomy on the gastric neuronal apparatus were studied ultrastructurally in five female dogs. A portion of the presynaptic terminals on neurons of the Auerbach's and Meissner's plexuses degenerated. The residual terminals presumably arose from intrinsic neurons. The neurons were of several types: (a) large motor neurons with synaptic connections that could not be distinguished from one another morphologically as to excitatory or inhibitory function and that underwent postdenervation changes and (b) presumed sensory neurons without detectable synaptic connections, which were unaffected by vagotomy, and which could be subdivided into two types. Other neuronal profiles with many large vesicles were observed only after vagotomy. The nerves to muscle layers contained small agranular vesicles and large dense-cored vesicles, sometimes with a predominance of one vesicle type or the other. It was not possible to determine whether these represented two morphological nerve types or sampling variations from a single structural type. Neither vesicle type seemed to be selectively affected by vagotomy. A few axons, presumably adrenergic, with small agranular vesicles, were observed, chiefly near blood vessels but also a few in the plexuses and in the muscle layers of the pyloric region. They were not obviously affected by vagotomy.

1768 THE INITIAL PHASE OF GASTRIC EMPTYING BEFORE AND AFTER VAGOTOMY AND PYLOROPLASTY.

(Eng.) Sheiner, H. J.; Thompson, I. J.; Hamilton, S. G. L.; Quinlan, M. F. (Perth Medical Center, Nedlands, Western Australia 6009, Australia). *Aust. N.Z. J. Surg.* 47(3):419-423; 1977.

The initial phase of gastric emptying of solid food was monitored in 10 normal subjects and in 12 patients who had undergone truncal vagotomy and pyloroplasty for duodenal ulcer at least 12 months previously. A gamma camera and on-line computer facilities were used for monitoring. In normal subjects, a consistent pattern was seen comprising an early delay in the onset of emptying (plateau), followed by an exponential decay curve. After vagotomy, the plateau was lost, and the exponential pattern of emptying began once the stomach was full. There was no evidence of sudden "dumping" of contents from the stomach. The overall rates of emptying as measured by the half-emptying time were the same in normal and postvagotomy patients. The faster initial phase of emptying after vagotomy is probably due to a loss of the normal plateau rather than to a sudden precipitous dumping of food out of the stomach.

1769 GASTRIC EMPTYING IN THE RAT IS INHIBITED B THE DUODENAL ULCEROGENS, CYSTEAMINE AND PROPIONITRILE.

(Eng.) Lichtenberger, L. M.; Szabo, S.; Reynolds, E. S. (Univ. Texas Medical Sch. at Houston, 6400 W. Cullen, Houston, TX 77030). *Gastr enterology* 73(5):1072-1076; 1977.

The effect of cysteamine (28 mg/100 g, intragastrically) or propionitrile (6 mg/100 g, s.c.) on gastri emptying was investigated by measuring the disappearance of intragastrically administered [^{57}Co]-vitamin B_{12} from the stomach of rats pretreated with these drugs or with water (controls). When either of the test compounds was administered 4 hr before the indicator, the gastric emptying rate was markedly retarded; the calculated half-time of removal of the [^{57}Co]vitamin B_{12} was 12 min, 56 min, and 104 min in rats given water, cysteamine, and propionitrile, resp. Gastric emptying was still significantly retarded 24 hr after the administration of cysteamine. The maximum effect of cysteamine, however, occurred 30 min after drug administration. Subsequent studies demonstrated that pyloroplasty was ineffective, whereas vagotomy completely blocked cysteamine-induced gastric retention. The duodenal ulcerogens therefore, may act like other factors that retard gastric emptying by acting on a vagally-dependent property of the proximal stomach to accommodate increasing volumes of liquid. These results suggest the possibility that this action of cysteamine and propionitrile to delay gastric emptying may be required for experimental ulcer formation.

1770 A MODEL FOR TREATING POST-IRRADIATION NAUSEA AND VOMITING IN MAN: THE ACTION OF INSULIN IN ABOLISHING RADIATION-INDUCED DELAY IN GASTRIC EMPTYING IN THE RAT. (Eng.) Hulse, E. V.; Patrick, G. (M.R.C. Radiobiology Unit, Harwell, Didcot, Oxon OX11 ORD, England). *Br. J. Radiol.* 50(597):645-651; 1977.

Radiation-induced delay of gastric emptying in rats, which may be comparable to radiation-induced nausea and vomiting in man, was successfully treated with insulin. After 200 R of whole-body x-ray exposure, the stomach of rats rarely showed any evidence of emptying over a 7-hr observation period. When a dose of 1.0 U of soluble insulin was given s.c. immediately after the first post-irradiation radiograph, the stomach began to empty immediately and continued to empty much faster than in unirradiated controls. Biphasic insulin, given immediately after the first post-irradiation radiograph, overcame radiation-induced gastric delay, but was without the precipitate emptying characteristic of soluble insulin. After 200 R of whole-body x-ray exposure, a dose of 0.5 U of biphasic insulin resulted in a stomach emptying rate that was virtually the same as that of unirradiated controls; with larger biphasic insulin doses, the stomach emptying rate was faster than in controls, and with smaller doses, the effect was proportionally reduced. Patterns of response to biphasic insulin were similar with larger radiation doses; an insulin dose of 1.0 U was required to restore normal gastric emptying after 600 R of x-rays, and a dose of 2.5 U was needed after 1,000 R of x-ray exposure. There was no simple correlation between the hypoglycemic action of insulin and its effect on stomach emptying. For example, in rats fed a barium meal containing malted milk and exposed to 200 R of x-rays, 0.1 U of insulin partially restored gastric emptying, but did not lower the plasma glucose level. Additional work is required to determine whether enteroglucagon or other intestinal hormones are involved in the actions of radiation and insulin on gastric motility. It is suggested that the use of insulin to treat radiation-induced nausea and vomiting in humans should be considered.

1771 MODIFYING EFFECT OF BRADYKININ ON MOTOR ACTIVITY IN THE GUINEA-PIG GALL BLADDER. (Eng.) Stasiewicz, J.; Szalaj, W.; Gabryelewicz, A. (Gastroenterology Clinic, Str. M.C. Sklodowskiej 24a, 15-276 Bialystok, Poland). *Clin. Exp. Pharmacol. Physiol.* 4(6):561-564; 1977.

The interaction of bradykinin and cholecystokinin preparations was investigated in the isolated guinea pig gallbladder. Bradykinin (1-100 ng/ml) induced dose-dependent contractile effects that were considerably smaller than those produced by cholecystokinin octapeptide. A low bradykinin concentration (1.0 ng/ml) caused a significant increase of the contraction induced by cholecystokinin octapeptide ($p<0.001$) and natural cholecystokinin-pancreozymin ($p<0.01$), and also augmented the effects of acetylcholine on this preparation. These effects are thus probably not specific for cholecystokinin.

1772 EFFECT OF VASOACTIVE INTESTINAL POLYPEPTIDE ON BASAL AND CHOLECYSTOKININ-INDUCED GALLBLADDER PRESSURE. (Eng.) Ryan, J.; Cohen, S. (Temple Univ. Sch. Medicine, Philadelphia, PA 19140). *Gastroenterology* 73(4, Part 1):870-872; 1977.

The pressure response of the opossum gallbladder to vasoactive intestinal polypeptide (VIP) alone and in combination with cholecystokinin (CCK) was studied *in vivo*. VIP alone (2.4 and 8 μg/kg/hr) produced dose-related decreases in basal gallbladder pressure ($p<0.05$). VIP eliminated spontaneous contractile activity when present, and it significantly antagonized the expected pressure response to CCK infusion. These observations support the proposal that the regulation of gallbladder motility depends upon the actions and interactions of the gastrointestinal hormones on gallbladder smooth muscle.

1773 CONDUCTION OF ACTIVITY BETWEEN MUSCLES IN THE TERMINAL REGION OF THE COMMON BILE DUCT AND IN THE NEIGHBORING DUODENUM. (Eng.) Nakayama, S.; Fukuda, H. (Okayama Univ. Medical Sch., Okayama 700, Japan). *Acta Med. Okayama* 30(1):21-35; 1976.

The relationship between muscle activity at the terminal region of the common bile duct and the duodenal muscle was examined in rabbits. Rhythmic muscle activity in the terminal region was synchronous with duodenal muscle activity. The activity of the latter muscle preceded the former. The activity at the terminal region synchronous with the rhythmic activity of the duodenal muscle sometimes disappeared spontaneously. At times, the muscle activity of the ampulla and the sphincter at the terminal region was independently lost. The conduction of excitation from the duodenal muscle to the terminal region appeared to occur at several sites. A "conduction-shunt path" probably exists between the terminal region and the duodenum, as well as between the ampulla and the sphincter. Some quantitative differences were found between the sphincter, ampulla, and duodenum in inhibitory effects to stimulation of splanchnic nerves and reflex effects and to excitatory effects of cholecystokinin-pancreozymin and cerulein. These results indicate that the sympathetic nerves and the intramural cholinergic neurons controlling the duodenal muscle and the terminal common bile duct muscles carry out activities quantitatively different from each other.

1774 INHIBITION BY VIP AND SECRETIN OF THE LOWER ESOPHAGEAL SPHINCTER PRESSURE IN MAN [Abstract]. (Eng.) Domschke, W.; Lux, G.; Domschke, S.; Strunz, U.; Rosch, W.; Bloom, S. R.; *et al.* (Dept. Medicine, Univ. Erlangen-Nurnberg, Erlangen, W. Germany). *Acta Hepatogastroenterol. (Stuttg.)* 24(6):484-485; 1977.

1775 REFLUX OF DUODENAL CONTENTS INTO THE CANINE PANCREATIC DUCT [Abstract]. (Eng.) Hendricks, J. C.; DiMagno, E. P.; Dozois, R. R.; Go, V. L. W. (Mayo Clinic, Rochester, MN). *Clin. Res.* 25(4):607A; 1977.

SECRETION AND METABOLISM

1787 ENZYMATICALLY IODINATED HUMAN SALIVARY PROTEINS: FRACTIONATION AND CHARACTERIZATION BY COLUMN CHROMATOGRAPHY AND ELECTROFOCUSING. (Eng.) Sarimo, S. S.; Tenovuo, J. (Dept. Biochemistry, Univ. Turku, SF-20500 Turku 50, Finland). *Biochem. J.* 167(1):23-29; 1977.

Enzymically [^{125}I]iodinated human salivary proteins were analyzed by diethylaminoethane (DEAE)-cellulose chromatography, column electrofocusing, and thin-layer polyacrylamide-gel (flat-bed) electrofocusing. The salivary proteins were enzymically iodinated by the ^{125}I-lactoperoxidase system. Salivary proteins were found to differ in their susceptibility to iodination carried out by this enzymic method. Two major iodine-binding protein fractions were discovered; one behaved like serum albumin on electrofocusing and was most susceptible to iodination by lactoperoxidase, and the other had pI characteristics similar to those of salivary amylase. The results suggest that iodoproteins may occur in human saliva. The significance of these iodoproteins may be related to the nonthyroidal metabolism of iodine.

1788 GLYCOPROTEIN SECRETION IN THE MOUSE SUBMANDIBULAR GLAND AS REVEALED BY RADIOAUTOGRAPHY AFTER L-^{3}H-FUCOSE INJECTION. (Eng.) Lima, T. G.; Haddad, A.; Fava-de-Moraes, F. (Instituto de Ciencias Biologicas, Universidade Federal de Minas Gerais, Caixa Postal 2486, 30000 Belo Horizonte/MG, Brazil). *Cell Tissue Res.* 183(4): 519-530; 1977.

Glycoprotein secretion was investigated by light microscope radioautography of semi-thin sections of the mouse submandibular gland after the administration of L-^{3}H-fucose (0.5 mCi, i.v.). The incorporation of the precursor in the acini was negligible. ^{3}H-fucose was taken up in the paranuclear region of the cells lining the intercalated, secretory, striated, and excretory ducts. This labeling pattern was interpreted as addition of the precursor to glycoproteins within the Golgi apparatus. Incorporation in the intercalated duct was restricted to the cells with fine cytoplasmic granules. The glycoproteins synthesized by the intercalated and secretory ducts were transported to the saliva by the secretion granules. It is assumed that the glycoproteins synthesized in the striated and excretory ducts are plasma membrane glycoproteins, which seem to renew continuously. Quantitation of the radioautographs supplied data concerning the incorporation of ^{3}H-fucose into newly synthesized glycoproteins as well as the renewal of the labeled macromolecules in each duct.

1789 INFLUENCE OF FOOD ON THE EFFECT OF 1-HYOSCYAMINE AND BENZILONIUMBROMIDE [Abstract]. (Eng.) Post, C.; Walan, A. (Dept. Clinical Pharmacology, Linkoping, Sweden). *Scand. J. Gastroenterol.* 12(Suppl. 45):72; 1977.

SECRETION AND METABOLISM

Stomach

1792 CYCLIC AMP AND CYCLIC GMP LEVELS IN GLANDULAR STOMACH OF RESTRAINED RATS. (Eng.) Zarrindast, M. R.; Sharghi, G.; Gerayesh-Nejad, S.; Djahanguiri, B. (Sch. Medicine, Univ. Tehran, Tehran, Iran). *Res. Commun. Chem. Pathol. Pharmacol.* 18(2):373-376; 1977.

Cyclic AMP and cyclic GMP were measured in the glandular stomach of Sprague-Dawley rats subjected to saline administration, cold (4 C), restraint, and restraint plus cold stress after 15, 30, 60, 90, and 120 min to determine the possible relationship between cyclic nucleotides and the development of stress ulcers. All animals subjected to restraint plus cold had gastric ulceration after 2 hr. A significant but transient decrease in cyclic AMP was observed 15 min after restraint plus cold. A marked, sustained and significant decrease of cyclic GMP was observed in the same group of animals. It seems unlikely that there is a correlation between cyclic AMP and cyclic GMP changes of the stomach and restraint-induced gastric ulceration.

1793 EFFECT OF ACETYLSALICYLIC ACID ON THE AMPHIBIAN GASTRIC MUCOSA. I. ELECTROPHYSIOLOGICAL AND PERMEABILITY CHANGES. (Eng.) Spenney, J. G.; Bhown, M. (Dept. Medicine, Univ. Alabama in Birmingham, Birmingham, AL 35294). *Gastroenterology* 73(4):785-789; 1977.

To study mechanisms by which aspirin alters ion transport in the stomach, electrophysiological and permeability changes were studied in the *in vitro* bullfrog gastric mucosa after an exposure of 10 or 20 mM acetylsalicylic acid. The potential difference and resistance rose initially. After 15 to 30 min of exposure, the potential difference declined to zero. Transmucosal resistance remained elevated considerably longer, but began to decline toward zero after 30-60 min of exposure. Mucosal permeability to mannitol increased as transmucosal resistance declined, but was not markedly elevated until the second hour of exposure to acetylsalicylic acid. The initial rise of potential difference was associated with inhibition of H^+ secretion, whereas the later decline of potential difference was due to inhibition of Cl^- transport. The abolition of short circuit current could not be attributed to mucosal to serosal flux of acetylsalicylate.

1794 EFFECT OF ACETYLSALICYLIC ACID ON GASTRIC MUCOSA. II. MUCOSAL ATP AND PHOSPHOCREATINE CONTENT, AND SALICYLATE EFFECTS ON MITOCHONDRIAL METABOLISM.

(Eng.) Spenney, J. G.; Brown, M. (Dept. Medicine, Univ. Alabama, University Station, Birmingham, AL 35294). *Gastroenterology* 73(5):995-999; 1977.

The effects of acetylsalicylic acid on gastric mucosal ATP, phosphocreatine, and O_2 consumption were studied *in vitro* in the bullfrog gastric mucosa. Potential difference and resistance changed rapidly after exposure to 10 or 20 mM acetylsalicylic acid at pH 3.0, 4.0, or 6.0 in the mucosal solution. ATP and phosphocreatine content decreased rapidly after exposure. Control mucosae contained 11.8 ± 0.98 nmol ATP and 11.5 ± 0.68 nmol of phosphocreatine per mg of protein. ATP content decreased by 21% and phosphocreatine by 45% after 15-30 min of exposure. Longer durations of exposure reduced both ATP and phosphocreatine levels to 10-15% of the controls. Oxygen consumption was increased during the first 15-30 min after exposure to acetylsalicylate. Longer durations of exposure reduced O_2 consumption to near control levels. Acetylsalicylate itself did not significantly affect mitochondrial respiration, respiratory control ratio, or ADP:O ratio. Salicylate had a biphasic effect that was concentration-dependent. Salicylate initially stimulated and later inhibited mitochondrial respiration. Using various substrates, the site of inhibition appeared to be located in the segment of the respiratory chain between coenzyme Q and cytochrome c_1. It is proposed that acetylsalicylate-induced mucosal injury includes absorption by diffusion from the acid contents of the lumen. Intracellularly, acetylsalicylic acid is hydrolyzed by an esterase to yield salicylate in sufficient concentration to uncouple and/or inhibit mitochondrial oxidative phosphorylation. As a result, ATP and phosphocreatine content decline, and many synthetic and transport activities cease.

1795 EFFECTS OF PROLONGED METIAMIDE MEDICATION ON THE FUNDIC MUCOSA: A SECRETORY AND HISTOMORPHOMETRIC STUDY IN THE RAT.

(Eng.) Witzel, L.; Halter, F.; Olah, A. J.; Hacki, W. H. (Inselspital, CH-3010 Berne, Switzerland). *Gastroenterology* 73(4):797-803; 1977.

Secretory and histomorphometric studies were carried out to determine the effect of long-term metiamide treatment on the parietal cell mass. Two groups of 10 rats each were treated with metiamide (200 mg/kg, s.c.) or with saline (0.15 M, 2 ml/kg, s.c.) at 8-hr intervals over 18 days. Eight hours after cessation of the treatment, basal secretion was not significantly altered, except for increased H^+ concentration in the metiamide group. Pentagastrin stimulation led to a significant rise in gastric juice volume (+18%), H^+ concentration (+50%), and acid output (+27%). In saline-treated controls no changes were observed. In the fundic mucosa, there was a significant increase in total number (+15%), total volume (+29%), and volume density (+11%) of parietal cells. These changes were attributable to increased volume of the individual parietal cell (+13%) and to increased fundic mucosal volume (+18%). Stimulated acid output correlated closely with both the total number and total volume of parietal cells. In an additional group of 10 rats, the mean serum gastrin levels rose significantly 2 hr after a single injection of metiamide (200 mg/kg, s.c.) in fasted and nonfasted conditions. It is concluded that in the rat prolonged administration of metiamide induces hypertrophy of the parietal cells, probably via hypergastrinemia, and leads to gastric hypersecretion after discontinuation of the medication.

1796 EFFECTS OF 7-OXA-13-PROSTYNOIC ACID (7-OPyA) AND PROSTAGLANDIN E_1 METHYL ESTER ON CANINE GASTRIC SECRETION.

(Eng.) Dajani, E. Z.; Driskill, D. R. (Dept. Biological Res., Searle Lab., P.O. Box 5110, Chicago, IL 60680). *Prostaglandins* 14(4):659-666; 1977.

The effects of 7-oxa-13-prostynoic acid (7-OPyA) on prostaglandin E_1 (PGE_1)-induced inhibition of gastric secretion were studied in unanesthetized dogs. Secretion was stimulated by the continuous i.v. infusion of histamine (1.0 mg/hr). At the steady-state plateau of gastric secretion, PGE_1 methyl ester (PGE_1 ME, 1.0 µg/kg/min) or PGE_1 ME and 7-OPyA (20-50 µg/kg/min) were simultaneously infused i.v. The extent of gastric secretory inhibition afforded by PGE_1 ME alone or in the presence of 7-OPyA was assessed. 7-OPyA did not modify PGE_1 ME gastric antisecretory actions when administered at doses 20-50 times greater than the dose of PGE_1 ME. These results suggest that the prostaglandin antagonist effects of 7-OPyA show organ specificity, which finding may be of clinical importance.

1797 ANTROPYLORIC G-CELL HYPERPLASIA IN HYPERCALCEMIC RABBITS BEARING THE VX_2 CARCINOMA

(Eng.) Dayal, Y.; Voelkel, E. F.; Tashjian, A. H., Jr.; DeLellis, R. A.; Wolfe, H. J. (New England Medical Center Hosp., 171 Harrison Ave., Boston, MA 02111). *Am. J. Pathol.* 89(2):391-400; 1977.

The distribution and the numbers of G cells in the gastric antropyloric region of hypocalcemic rabbits bearing the VX_2 carcinoma were mapped employing immunoperoxidase localization and morphometric quantitation and compared with that in the normal rabbit stomach. In normal animals, G cells were confined to the lower third of the antropyloric mucosa, where they were randomly distributed within the mucosal glands. In contrast, tumor-bearing animals showed an extension of these cells into the middle third of the antropyloric mucosa. The absolute counts of G cells in control rabbits were 5.3 ± 0.78 per unit area, while those in hypercalcemic tumor-bearing rabbits were 11.9 ± 0.46 per unit area ($p<0.05$). It is concluded that rabbits bearing the VX_2 carcinoma have G-cell hyperplasia.

1798 LOCALIZATION OF GASTRIN RECEPTORS IN INTACT ISOLATED AND SEPARATED RAT FUNDIC CELLS. (Eng.)

Soumarmon, A.; Cheret, A. M.; Lewin, M. J. M. (Hopital Bichat, 170 Boulevard Ney, Paris 75018, France). *Gastroenterology* 73 (4):900-903; 1977.

The cellular localization of previously described "high affinity" receptor sites ($K=0.60-0.80\ 10^{-8}$) for gastrin in purified plasma membranes from rat fundic mucosa was investigated. Dispersed rat fundic cells were prepared by pronase dissociation. Populations of 10% to 70% "large cells" (i.e., parietal cells) were obtained by successive 100 x *g* 45-sec centrifugations. Of the cells, 93 ± 5% excluded trypan blue; oxygen consumption ranged from 3.5 (10% large cells) to 15 nmol O_2/min/10^6 cells (70% large cells); cell ultrastructural integrity was well preserved. ^{3}H-labeled G17-I binding to isolated cells was temperature-dependent, proportional to cell concentration, reversible, and a saturable process as a function of time and hormone concentration. Association and dissociation rate constants were $K_1=0.69 \times 10^7$/M/min and $K_{-1}=0.063$/min, resp., at 20 C, pH 7.4. A Scatchard plot of the binding suggested a single class of binding sites with an equilibrium constant $K=0.90 \times 10^{-8}$ M and a maximum binding capacity of 7,500 sites per cell (crude suspension). Binding increased linearly as a function of the enrichment in parietal cells, the theoretical maximum binding capacity (100% parietal cell population) being 14,000 to 19,000 sites per cell. These findings on intact fundic cells compare favorably with those previously found on their derived plasma membranes. It is therefore suggested that, in the rat, parietal cells contain the high affinity gastrin receptors.

1799 THE GASTRIN-PRODUCING CELLS IN TISSUE CULTURES OF THE RAT PYLORIC ANTRUM. (Eng.)

De Schryver-Kecskemeti, K.; Greider, M. H.; Saks, M. K.; Rieders, E. R.; McGuigan, J. E. (Div. Surgical Pathology, Washington Univ., St. Louis, MO 63110). *Lab. Invest.* 37(4):406-410; 1977.

Tissue culture methods for the study of gastrin-producing cells isolated from the pyloric antral mucosa of male Wistar rats are described. Gastrin cell cultures were maintained for up to 7 days, with the largest number of well-defined cells seen on days 3 and 4. Gastrin cells were identified by means of immunofluorescent and unlabeled antibody-enzyme techniques. The tissue culture medium was monitored for basal gastrin secretion. In addition, stimulation of gastrin release was achieved by the use of dibutyryl cyclic-AMP and theophylline. The fact that gastrin cell cultures responded specifically and repetitively to stimulation supports the conclusion that this tissue culture approach maintains functional integrity of the gastrin cell and may be used to study the regulatory mechanism of gastrin secretion.

1800 STRUCTURE-FUNCTION RELATIONSHIPS OF PEPTIDE FRAGMENTS OF GASTRIN AND CHOLECYSTOKININ. (Eng.)

Kaminski, D. L.; Ruwart, M. J.; Jellinek, M. (Saint Louis Univ. Sch. Medicine, St. Louis, MO 63104). *Am. J. Physiol.* 233(4):E286-E292; 1977.

The structure-function relationships of the C-terminal peptide fragments of gastrin and cholecystokinin (CCK) were evaluated in the canine biliary system and the stomach. Dogs with chronic biliary and gastric fistulas were used. The administration of the common fragments of cholecystokinin (CCK) and gastrin with four and five amino acids and the active fragments of CCK with six through eight amino acids without sulfation of tyrosine in position 7 failed to alter hepatic bile flow from control values, while they significantly stimulated gastric hydrogen ion output. The administration of the seven and eight amino acid peptide fragments of CCK with sulfation of tyrosine in position 7 significantly increased hepatic bile flow. The administration of the sulfated octapeptide with 4 μg/kg/hr of nonsulfated octapeptide did not result in the inhibition of the choleresis produced by the sulfated peptide. The gastric hydrogen ion response produced by the administration of the nonsulfated and sulfated peptide was equal to that of the nonsulfated peptide alone. These results suggest that in the biliary system the receptor is highly specific as sulfation of the peptide fragment of CCK is essential for combining with the receptor, whereas in the stomach the receptor has little specificity and combines with all of the peptide fragments evaluated.

1801 RELEASE OF ANTRAL AND DUODENAL GASTRIN IN RESPONSE TO AN INTESTINAL MEAL. (Eng.)

Llanos, O. L.; Villar, H. V.; Konturek, S. J.; Rayford, P. L.; Thompson, J. C. (Univ. Texas Medical Branch, Galveston, TX 77550). *Ann. Surg.* 186(5): 614-618; 1977.

The release of antral and duodenal gastrin was studied during the intestinal phase of gastric secretion, and the influence of the pH of the meal and of the antrum on the release of antral and duodenal gastrin was investigated. In dogs prepared with isolated, innervated antral pouches, intraduodenal perfusion with liver extract at pH 7, with the antrum buffered at pH 7, resulted in a significant release of gastrin selectively from the antrum (from 118 ± 13 pg/ml to 261 ± 58 pg/ml) and from the duodenum (124 ± 25 to 404 ± 100 pg/ml). Acidification of the meal to pH 1 abolished both antral and duodenal gastrin release, whereas acidification of the antrum abolished only the antral gastrin response. After antrectomy, liver extract at pH 7 caused a diminished but significant release of duodenal gastrin. These studies indicate that an intestinal meal may release (in addition to a specific intestinal phase hormone) gastrin from the intestine and from antrum, by means of a pH-sensitive mechanism that may involve a humoral agent from the small bowel.

1802 STIMULATION OF GASTRIN RELEASE AND GASTRIC SECRETION BY AMINO ACIDS BATHING PYLORIC GLAND AREA.

(Eng.) Konturek, S. J.; Tasler, J.; Cieszkowski, M.; Dobrzanska, M.; Wunsch, E. (Medical Acad., Krakow, Poland). *Am. J. Physiol.* 233 (3):E170-E174; 1977.

The potency of L- and D-isomers of 18 natural amino acids (AA) bathing the pyloric gland area in stimulating gastrin release and gastric acid secretion was compared in three dogs with denervated antral (AP) and Heidenhain pouches (HP) and gastric fistulas (GF). L-isomers of all natural AA stimulated acid secretion from the HP, whereas D-isomers were significantly less effective. The most potent L-isomers of AA were phenylalanine, alanine, and glycine, which caused an increase in acid output reaching 36%, 29%, and 26%, resp., of the maximal response to histamine (MRH). The strongest stimulants of acid secretion were relatively weak releasers of gastrin. Irrigation of the AP with increasing concentrations of L-phenylalanine (0.1-0.8 M), liver extract (2.5-20%), and acetylcholine (0.1-0.8%) resulted in a stepwise increase in acid reaching 31%, 22%, and 12% of the MRH, resp. Three gastrin peptides (G-14, G-17, and G-34), infused in graded doses (6.2-100 pmol/kg/hr), produced a dose-related increase in acid output, reaching 25%, 17%, and 17%, resp., of the MRH. The increment in serum gastrin was also dose-related and similar with G-14 and G-17 administration but significantly higher with G-34 administration. All L- and, to a lesser degree, D-isomers of natural AA bathing the pyloric gland area caused stimulation of gastric acid secretion that can be only partially explained by release of the major gastrin peptides.

1803 OPPOSITE EFFECTS OF GASTRIN ON CELL PROLIFERATION IN THE ANTRUM AND OTHER PARTS OF THE UPPER-GASTROINTESTINAL TRACT IN THE RAT.

(Eng.) Casteleyn, P. P.; Dubrasquet, M.; Willems, G. (St. Pierre Hosp., Hoogstraat, 322, B 1000 Brussels, Belgium). *Am. J. Dig. Dis.* 22(9):798-804; 1977.

The effect of gastrin on DNA synthesis and mitotic activity in the mucosa of the upper gastrointestinal tract was examined by autoradiography in unanesthetized Wistar rats with a gastric fistula. Animals were killed at 4-hr intervals, after starting a 3-hr i.v. infusion with the lowest dose of gastrin provoking a maximal acid output. Tritiated thymidine was injected 1 hr before killing. Labeling and mitotic indices were estimated in the fundic, antral, duodenal, and jejunal mucosa. The proliferative activity in the fundic, duodenal, and jejunal glands was significantly increased 16 hr after gastrin administration. In the antral glands, however, a significant decrease in both labeling and mitotic indices was observed ($p<0.05$ and $p<0.01$, resp.). Rhythmic variations in proliferative activity were observed in the antral, duodenal, and jejunal mucosa in controls. They were different from those in the gastrin-treated animals. The data confirm the trophic action of gastrin in the fundic, duodenal, and jejunal mucosa. They also indicate an inhibitory effect of this hormone on cell proliferation in the antral mucosa.

1804 THE EFFECT OF ATROPINE ON ACID SECRETION STIMULATED BY ACETYLCHOLINE, HISTAMINE AND GASTRIN IN THE ISOLATED WHOLE STOMACH OF THE RAT.

(Eng.) Bunce, K. T.; Marsh, G. F.; Parsons, M. E. (Smith Kline and French Lab. Ltd., Welwyn Garden City, Hertfordshire, England). *Br. J. Pharmacol.* 61(2):279-284; 1977.

Isolated stomach preparations from immature rats were used to study the effect of atropine on gastric acid secretion stimulated by histamine, gastrin, and acetylcholine. The acid secretory response to acetylcholine was not inhibited by 0.3 μM atropine. Atropine at 1 to 3 μM produced a measurable inhibition of acid secretion, and atropine at 10 μM caused a complete block of acid secretion, which could not be surmounted by high concentrations of acetylcholine (3-10 mM). The acid secretory response to histamine was not inhibited by concentrations of up to 1 mM of atropine. Atropine concentrations of 1 μM and 10 μM did not inhibit gastrin-stimulated acid secretion, although a significant inhibition of acid output was observed at atropine concentrations of 0.1 mM and 1 mM.

1805 DUODENAL ULCEROGENS, CYSTEAMINE AND PROPIONITRILE, STIMULATE SERUM GASTRIN LEVELS IN THE RAT.

(Eng.) Lichtenberger, L. M.; Szabo, S.; Trier, J. S. (Univ. Texas Medical Sch., P.O. Box 20708, Houston, TX 77025). *Gastroenterology* 73(6):1305-1308; 1977.

To determine the role of gastrin in the mechanism by which cysteamine and propionitrile induce duodena ulcer formation, these drugs were administered to fasted female Sprague-Dawley rats, and their effect on fasting and food-stimulated serum gastrin levels was studied. Intragastric administration of cystea mine (28 mg/100 g) caused a three- to fourfold increase in fasting serum gastrin levels over the val ues of controls. Propionitrile (6-12 mg/100 g) was a less effective stimulant of gastrin release, causing a 1.5- to 2-fold increase in gastrin levels over matched controls. The food-stimulated rise in serum gastrin levels after either a chow meal or intragastric instillation of a peptone solution was markedly enhanced by cysteamine pretreatment. Three hours after feeding, the serum gastrin levels of cysteamine-pretreated rats were six times higher than those of fed controls. The high serum gastri levels of cysteamine-pretreated fed rats could not be explained solely by the additive effects of cysteamine and food, indicating that a potentiating interaction may exist between the two stimulants of gastrin release. The importance of this drug-induced stimulation of gastrin release, under both fasted and fed conditions, in the ulcerogenic process has yet to be ascertained.

1806 ON THE CAUSE OF THE INCREASED HEIDENHAIN POUCH SECRETION AND SERUM GASTRIN CONCENTRATION AFTER GASTROJEJUNOSTOMY IN DOGS: WITH A STATISTICAL APPENDIX.

(Eng.) Rokkjaer, M.; Host, V.; Brandsborg, O.; Brandsborg, M.; Lovgreen, N. A. (Kommunehospitalet, DK-8000 Aarhus C, Denmark). *Gastroenterology* 73(5):1065-1071; 1977.

The possible importance of reduced duodenal inhibition of gastric acid secretion, reflux or regurgitation of alkaline duodenal contents, gastric stasis resulting from gastrin release, and increased intestinal stimulation of gastric secretion in the increased Heidenhain pouch (HP) secretion seen after gastrojejunostomy (GEA) in dogs was investigated. In 10 dogs with HP, a GEA was constructed and later converted into a Roux-en-Y anastomosis to abolish or reduce trans-stomal reflux. Next, duodenal inhibition was abolished by duodenal transection, and finally the duodenal bulb was excised. The 24-hr HP acid output increased after GEA, some 70% of the increase being attributable to trans-stomal reflux, the rest to decreased duodenal inhibition. Abolished duodenal inhibition caused a new rise, not significantly different from that caused by the combined effect of reflux, and decreased duodenal inhibition after GEA. The 24-hr fasting HP acid output and 5-hr food-stimulated HP acid output rose after GEA by the same amount as that caused by abolished duodenal inhibition. A significant correlation was found between integrated gastrin and total HP acid output after food stimulation. Both fasting and food-stimulated gastrin concentration rose after GEA, the latter caused by reflux alone. Elimination of duodenal inhibition caused an unexpected rise in both fasting and food-stimulated gastrin concentration.

1807 EFFECT OF MULTIPLE-STRESS PROCEDURES ON MONKEY GASTRODUODENAL MUCOSA, SERUM GASTRIN, AND HYDROGEN ION KINETICS.

(Eng.) Natelson, B. H.; Dubois, A.; Sodetz, F. J. (New Jersey Medical Sch., 88 Ross St., East Orange, NJ 07018). *Am. J. Dig. Dis.* 22(10):888-897; 1977.

The effect of frequently changing and stressful performance demands on the condition of the gastroduodenal mucosa, the serum gastrin level, and H^+ kinetics was studied in rhesus monkeys. By arranging a series of psychological contingencies (unpredictability, uncontrollability, conflict), coupled with delivery of a physical stimulus (electric shock), gastroduodenal mucosal lesions were produced in seven of eight monkeys. The most severe conflict paradigm most consistently produced lesions across subjects. Of the 30 lesions observed by endoscopy, 80% occurred near the anatomic junction of gastric body and antrum, in the antrum, or in the duodenum. Lesions varied in severity from discolorations of the mucosa to disruptions of mucosal integrity. Gastric lesions generally disappeared in several days, despite the continuation of stress; some duodenal lesions were equally evanescent, but in two monkeys, lesions lasted over 1 week. Hydrogen ion kinetics were measured in two monkeys that developed gastric lesions and two that developed duodenal lesions. The rate at which hydrogen ion entered the duodenum was uniformly suppressed for all four monkeys during their first session of shock avoidance; during their last session, the gastric subgroup continued to show suppression while the duodenal subgroup returned towards control levels. Serum gastrin levels were unchanged by the multiple stress procedures. The finding of consistently producible, stress-induced gastroduodenal pathology in anatomic areas similar to those involved in man suggests that the subhuman primate is suitable for further efforts to produce an animal model of psychosomatic ulcer disease.

1808 EFFECTS OF FASTING AND PENTAGASTRIN ON PROTEIN SYNTHESIS BY ISOLATED GASTRIC MUCOSAL RIBOSOMES IN A CELL-FREE SYSTEM.

(Eng.) Nandi Majumdar, A. P.; Goltermann, N. (Inst. Medical Biochemistry, Univ. Aarhus, DK-8000 Aarhus C, Denmark). *Gastroenterology* 73(5):1060-1064; 1977.

Gastric mucosal polyribosomes, isolated from fasted, fed, and pentagastrin-treated fasted rats were studied for their ability to support protein synthesis in a cell-free system. Groups of Wistar rats were either fed *ad libitum* or fasted for 48 hr, and pentagastrin (500 μg/kg) was then injected to one fasted group, while the other fasted and fed groups received 0.9% saline. Liver cell sap, prepared from normal fed rats was used as a source for activating enzymes in the cell-free systems. The rate of [^{14}C]amino acid incorporation into protein by gastric mucosal polyribosomes from nonfasted and pentagastrin-injected rats was considerably higher than that of the fasted control. One hour after the hormone injection, ribosomal protein synthesis was 40% higher than in the control. However, 1.5 and 6 hr after the hormone treatment, the increments were 22% and 15% above the respective controls. A prolongation of the fasting period itself from 48 to 54 hr caused a 7% reduction in ribosomal protein synthesis. The protein to phenylalanine ratio, which represents a ratio of polysomes to monosomes, was 100% above the fasted controls 1 hr after pentagastrin injection. In the absence of polyuridylic acid [poly(U)], the incorporation of [^{14}C]phenylalanine into protein by polyribosomes from the pentagastrin-injected rats was 65% higher than the fasted control, whereas in the presence of poly(U), the control ribosomes showed a 20% increased incorporation. Polyphenylalanine synthesis by the control ribosomes was also 30% above the hormone-treated group. The more active response of the control ribosomes to poly(U) may be attributable to the presence of a higher proportion of monosomes in the preparation.

1809 EFFECT OF METHACHOLINE ON ACID AND PEPSIN RESPONSES TO PENTAGASTRIN IN CATS WITH INNERVATED AND DENERVATED FUNDIC POUCHES.

(Eng.) Svensson, S. O.; Dubrasquet, M.; Emas, S. (Karolinska Sjukhuset, Stockholm, Sweden). *Surgery* 82(5): 580-587; 1977.

The effect of threshold dose of methacholine (15 or 20 μg/kg/hr, i.v.) on gastric secretion stimulated by pentagastrin (PG) was studied in four cats with Pavlov pouches (PP) and in four with Heidenhain pouches (HP). In the PP group, methacholine did not alter either the maximal response (MR) or the dose producing half of the maximal response (D_{50}) for PG. In the HP group, the highest acid response to PG combined with methacholine was greater than the MR to PG alone. Methacholine decreased the D_{50} for PG in the HP group to that in the PP group with and without methacholine ($p<0.001$ and $p<0.05$, resp.). Methacholine increased the pepsin response to all doses of PG both in the PP ($p<0.001$) and the HP groups ($p<0.05$ to $p<0.001$). The effect was more pronounced in the HP group. In both types of pouches, the percentage increase of pepsin secretion was larger at low than at high doses of PG. Methacholine increased the pepsin/acid (P/A) ratio for PG in the HP group to that in the PP group with and without methacholine. Accordingly, methacholine sensitized the oxyntic glands and increased the pepsin response to PG in the HP group as did basal vagal tone in the PP group. Methacholine did not further sensitize the innervated oxyntic glands to gastrin but increased the response of the peptic glands. It is concluded that a threshold dose of methacholine produces equal sensitization of the oxyntic cells to PG in the HP as basal vagal tone in the PP but produces no further sensitization in the PP. A threshold dose of methacholine increases the acid secretory capacity only in the HP. The pepsin responses of the PP and HP to various doses of PG are increased by a threshold dose of methacholine, which also mimics basal vagal tone by increasing the P/A ratio for PG in the HP to that in the PP.

1810 COMPARISON OF THE INHIBITION OF HISTAMINE- AND PENTAGASTRIN-STIMULATED GASTRIC ACID SECRETION BY SOMATOSTATIN IN THE CAT.

(Eng.) Albinus, M.; Reed, J. D.; Gomez-Pan, A.; Schally, A. V.; Coy, D. H. (Dept. Pharmacology, Univ. Tubingen, Tubingen, W. Germany). *Agents Actions* 7(5/6):501-506; 1977.

The inhibitory effect of cyclic somatostatin on pentagastrin- and histamine-stimulated gastric acid secretion in normal and vagotomized gastric fistula cats was investigated. Histamine dose-response curve experiments in cats with intact vagus nerves showed that at low doses of histamine, 4 or 10 μg/kg/hr of somatostatin produced a significant reduction in gastric acid output, and at any one dose of histamine, this inhibition was somatostatin dose-dependent. However, as the dose of histamine was increased to produce maximum gastric secretory rates, neither 4 nor 10 μg/kg/hr of somatostatin produced inhibition of gastric acid output. The result was a dose-response curve converging with no inhibition at a histamine dose of 250 μg/kg/hr. The infusion of somatostatin (10 μg/kg/hr) during stimulation of gastric acid secretion by pentagastrin (8 μg/kg/hr) in cats with intact vagus nerves resulted in rapid inhibition of gastric acid secretion that reached 95% in the last 30 min of the somatostatin infusion. Following the end of this infusion, the gastric acid secretion rapidly returned to control values. With pentagastrin stimulation, somatostatin produced parallel displacement of the dose-response curves. It is suggested that somatostatin competitively inhibits pentagastrin-stimulated gastric acid secretion, whereas it inhibits histamine-stimulated secretion by a mechanism that is not competitive in nature. The vagus nerves seem to be involved in the mode of action of somatostatin, since the inhibitory effects of somatostatin were greater in vagotomized than in vagus-intact animals.

1811 ELECTRICAL EVENTS DURING ACTIVATION AND INHIBITION OF GASTRIC HCl SECRETION.

(Eng.) Rehm, W. S.; Sanders, S. S. (Medical Center, Univ. Alabama in Birmingham, University Station, Birmingham, AL 35294). *Gastroenterology* 73(4): 959-969; 1977.

Some of the relationships between the secretory rate and the electrophysiological characteristics of the canine and frog gastric mucosa are reviewed. There is no simple relationship between the potential difference (PD) and H^+ rate in the *in vitro* frog gastric mucosa with standard Cl^- bathing solutions. In contrast, with Cl^--free solutions (PD is inverted), there is a precise linear relation between the PD and the H^+ rate. This linear relationship strongly supports the concept that the H^+ mechanism under these conditions is electrogenic. In the past, it has been difficult to exclude the possibility that the inverted PD is due to a liquid junction potential between acid fluid in the lumina and the secretory bathing solution. The use of aminopyrine or imidazole essentially eliminates the possibility that the inverted PD is due to a liquid junction potential. Hence, the linear relationship is solid evidence for the electrogenicity of the H^+ mechanism. Recently, aminopyrine and imidazole have been shown to reverse thiocyanate inhibition of H^+ secretion.

1812 ABSOLUTE DEPENDENCE ON CHLORIDE FOR ACID SECRETION IN ISOLATED GASTRIC GLANDS.

(Eng.) Berglindh, T. (Biomedical Center, Univ. Uppsala, P.O. Box 572, S-751 23 Uppsala, Sweden). *Gastroenterology* 73(4):874-880; 1977.

To gain information concerning the nature of chloride transport and its interactions with H^+ secretion in the mammalian parietal cell, the behavior of isolated rabbit gastric glands in chloride-free solutions was studied. The glands lost their ability to accumulate H^+ ions when incubated in Cl^--free solutions, as measured by accumulation of the weak base aminopyrine (AP). Simultaneously, basal oxygen consumption was significantly increased (+56%). Addition of histamine or dibutyryl cyclic AMP (db-cAMP) further increased the respiration, but only a minor increment in the AP accumulation was seen. Addition of Cl^- dose-dependently increased he AP accumulation back to normal basal values, function that was coupled with a progressive lecrease in oxygen consumption down to the normal evel. ED_{50} for AP accumulation was 15.0 mM Cl^-. CN^- also decreased the respiratory rate, but did ot restore AP accumulation. Increasing the K^+ oncentration of the Cl^--free solution 10-fold did ot affect the AP ratio per se, but facilitated he rise in AP accumulation upon addition of Cl^-. t standard Cl^- concentrations the final AP ratio as significantly increased above that of glands ncubated at normal K^+ concentrations. The addiion of Br^- to the chloride-free medium induced esponses indistinguishable from those of Cl^-, hereas I^- showed less affinity and was inhibitory t higher concentrations (>20 mM). Studies on AP ccumulation kinetics showed that the addition of l^- to glands pretreated with db-cAMP did not inuce a more rapid accumulation than that seen in lands to which db-cAMP and Cl^- were added simulaneously. This might indicate that db-cAMP does ot induce a morphological transformation of the arietal cell into a secreting state in the absence f Cl^-. As one explanation for the results obtained, Cl^--HCO_3^- exchange mechanism in the secretory memrane is proposed, which implies that HCO_3^- handling the secretory membrane is impaired in the abence of Cl^- and that this could lead to a neutralzation of the H^+ ions formed.

13 EVIDENCE FOR A HISTAMINE H_2 RECEPTOR THAT INHIBITS PEPSIN SECRETION IN THE DOG.

ng.) Hirschowitz, B. I.; Hutchison, G. A. (Dept. edicine, Univ. Alabama, Birmingham, AL 35294). . *J. Physiol.* 233(3):E225-E228; 1977.

id and pepsin output were studied in four gastric stula dogs treated with histamine and in five gs treated with 4-methylhistamine [4(Me)H]. Each ine was given in 45-min incremental step doses constitute full dose-response curves (histamine: 5, 10, 20, 50, 100, and 150 µg/base/kg/hr; 4-thylhistamine: 1.5, 3.5, 7, 15, 35, 70, and 105 /kg/hr). Pepsin output was biphasic with both ugs. Peak pepsin output occurred at low doses 5 µg/kg/hr) and progressive inhibition of output s seen at higher doses, but H^+ output was stimated at all doses. Cimetidine (1 mg/kg/hr) comtitively inhibited H^+ stimulation. The pepsin sponse to histamine or 4(Me)H was converted to positive logsigmoid response when cimetidine s given at the same time. In the presence of metidine (1 mg/kg/hr), the outputs of H^+ and psin were positively correlated in the full stamine dose range. These data show that histane effects on pepsin secretion are a mixture stimulation and inhibition and that the recepr responsible for pepsin stimulation is of a gh affinity, low K_m, H_2 type, whereas inhibition high doses of histamine is probably mediated a low affinity, high K_m receptor, also H_2 type.

1814 EFFECT OF HISTAMINE RECEPTOR ANTAGONISTS ON BILE DAMAGE TO THE GASTRIC MUCOSA OF CANINE HEIDEHAIN POUCHES.

(Eng.) Rees, W. D. W.; Rhodes, J.; Wheeler, M. H.; Meek, E. M.; Williams, B.; Newcombe, R. G. (Univ. Hosp. Wales, Wales, Cardiff, Wales). *Gut* 18(10):821-826; 1977.

The effect of combined H_1 and H_2 histamine receptor antagonists (mepyramine maleate or metamide, resp.) on damage to the gastric mucosal barrier produced by sodium taurocholate was studied. Four mongrel dogs were prepared with gastric Heidenhain pouches two months before the experiment. Changes in the volume, ionic (H^+ and Na^+) concentrations and flux, and transmucosal potential difference were determined in three 30-min periods. In periods I and III, a standard acid solution was placed in a pouch, and in period II, bile (sodium taurocholate) was given. Dogs were also given i.v. injections of H_1 or H_2 receptor antagonists, alone or in combination (mepyramine maleate, 10 mg/kg during period I, or metamide, 200 µM/50 ml/hr throughout the experiment). In control experiments (normal saline, 50 ml/hr, i.v.), there was a small loss of the pouch fluid during period I, but the volume increased by 1.2 ml during period II ($p<0.01$); a small increase occurred in period III. There was a decrease in H^+ concentration, especially in period II (-4.7 µM/ml, $p<0.05$). An increase in Na^+ concentration was maximum in period II (+3.3 µM/ml, $p<0.025$). The changes in H^+ and Na^+ ion flux followed the pattern described for the changes in ion concentration. The transmucosal potential difference remained steady during period I (-43 mV); it decreased significantly in period II ($p=0.02$); and then increased during period III. Similar results were obtained when either H_1 or H_2 antagonists were given. The histamine content in pouch fluid was 0.030 µg/ml in controls and during period I; it increased to 0.066 µg/ml during period II. When H_1 and H_2 antagonists were given together, the comparable values were 0.055 µg/ml and 0.058 µg/ml, resp. The combined effect of H_1 and H_2 antagonists appears to reduce or abolish changes in the volume and ionic fluxes produced by sodium taurocholate. The results suggest that histamine mediates changes in the transmucosal ionic flux produced by bile acid.

1815 EFFECT OF ANTRECTOMY ON GASTRIC HYPERSECRETION INDUCED BY DISTAL SMALL BOWEL RESECTION.

(Eng.) Hall, A. W.; Moossa, A. R.; Wood, R. A. B.; Block, G. E.; Skinner, D. B. (Pritzker Sch. Medicine, Univ. Chicago, 950 E. 59th St., Chicago, IL 60637). *Ann. Surg.* 186(1): 83-87; 1977.

The mechanisms involved in the gastric hypersecretory response to distal small bowel resection were elucidated by studying the secretory profile, serial fasting serum gastrin, and gastric inhibitory polypeptide (GIP) in seven male Rhesus monkeys, with demonstrated gastric hypersecretory response to 50% distal small bowel resection. This increase in gastric acid output had persisted for more than 6 months. Precise, anatomical antrectomy without vagotomy was performed, and intestinal continuity restored by gastroduodenostomy. Complete abolition of basal acid secretion and of the secretory response to histamine occurred. These effects could not be reversed by continuous (5 hr) infusions of pentagastrin (0.2 μg/kg/hr or 2 μg/kg/hr). The dose response curve to gastrin pentapeptide was altered; maximum secretion was greatly reduced and occurred at 10 μg/kg/hr. Neither basal serum gastrin or basal serum GIP was significantly reduced by antrectomy. These findings indicate that, in this animal model, the antrum is essential in the genesis of the hypersecretory state. If these findings are relevant to man, precise antrectomy may be the procedure of choice for symptomatic acid hypersecretion after small bowel resection or disease.

SECRETION AND METABOLISM

Pancreas

1849 STUDIES OF THE SECRETORY PROCESS IN THE MAMMALIAN EXOCRINE PANCREAS. I. THE CONDENSING VACUOLES. (Eng.) Novikoff, A. B.; Mori, M.; Quintana, N.; Yam, A. (Albert Einstein Coll. Medicine, Yeshiva Univ., Bronx, NY 10461). *J. Cell Biol.* 75(1):148-165; 1977

Phosphatase cytochemistry was used to distinguish between the Golgi apparatus and the specialized region of endoplasmic reticulum at the inner (trans) aspect of the Golgi stack known as GERL, in pancreatic exocrine cells of guinea pig, rat, rabbit, and hamster. The trans element of the Golgi stack exhibited thiamine pyrophosphatase (TPPase) but no acid phosphatase (AcPase) activity. In contrast, GERL showed AcPase but no TPPase activity. The nascent secretory granules, or condensing vacuoles, were expanded cisternal portions of GERL. Continuities of condensing vacuoles with rough endoplasmic reticulum are suggested, and it is proposed that some secretory components may have direct access to the condensing vacuoles from endoplasmic reticulum. Connections of Golgi apparatus with GERL were not seen.

1850 INCORPORATION PATTERN OF L-, D-, AND DL-AMINO ACIDS INTO THE PANCREAS OF MICE. (Eng.) Goto, R.; Tezuka, M.; Tamemasa, O. (Shizuoka Coll. Pharmacy, 2-1, Oshika 2-chome, Shizuoka, Japan). *Chem. Pharm. Bull.* 25(7):1574-1581; 1977.

Comparative experiments were made on the *in vivo* incorporation of 18 kinds of ^{14}C-labeled L-amino acid, and of D- and DL-forms of four selected radioactive amino acids into the trichloroacetic acid (TCA)-soluble and protein fractions of the pancreas and liver of dd/Y mice to develop amino acid derivatives as new pancreas-scanning agents. Among the L-forms tested, tryptophan, valine, methionine, and leucine, in this order of decreasing incorporation, showed a relatively high incorporation into the pancreas 30 min after their i.v. injection. The pancreas/liver ratio of the radioactivity of methionine, valine, and leucine determined 15, 30, and 60 min after injection was 6:10. These three amino acids seem to be a possible mother compound for introducing γ-emitters as a pancreas-scanning agent. In the TCA-soluble fraction of the pancreas, the radioactivity of DL- or D-amino acids tested was higher than that of the corresponding L-amino acid. Almost all radioactivity of D-leucine was found in the TCA-soluble fraction. The incorporation of D-leucine into the pancreas was similar to that of L-leucine. These results suggest that γ-radiating derivatives of amino acids might be useful as new pancreas-scanning agents.

1851 IMMUNOHISTOCHEMICAL DEMONSTRATION OF GLUCAGON- AND GLI-CONTAINING CELLS IN THE CANINE GUT AND PANCREAS. (Eng.) Ito, S.; Kobayashi, S. (Niigata Univ. Sch. Medicine, Asahimachi-dori 1, Niigata, 951 Japan). *Arch. Histol. Jpn.* 39(3):193-202; 1976.

Cells with glucagon- and glucagon-like immunoreactivity (GLI) were studied by an indirect immunofluorescence technique in the normal canine gastrointestinal mucosa and pancreas. Glucagon immunoreactivity was demonstrated in the basal-granulated cells in the deeper portion of the fundic gland of the stomach as well as in the A cells of the pancreatic islet. GLI-positive basal-granulated cells were found in the gastric fundus, jejunum, ileum, and colon. These cells were not found in the pyloric antrum or duodenum. Careful examination of the immunofluorescence specimens indicated that essentially every GLI-positive cell in the gastric fundus and pancreas contained glucagon. The GLI-positive cells in the jejunum, ileum, and colon were the "open" type (i.e., reaching the lumen with their tapered luminal process), whereas the glucagon/GLI-positive cells in the stomach were "closed" (separated from the lumen by a layer of epithelial cells). Basal-granulated cells could receive information for their secretory activity from either the luminal or the serosal side of the gut mucosa.

1852 EFFECT OF ADRENOCORTICOTROPIC HORMONE ON PURE EXOCRINE PANCREATIC SECRETION IN MAN (Eng.) Gullo, L.; Costa, P. L.; Fontana, G.; Tessari, R.; Serra, D.; Labo, G. (Istituto di Clinica Medica e Gastroenterologia, Ospedale S. Orsola, 40138 Bologna, Italy). *Gastroenterology* 73(4, Part 1):763-764; 1977.

The effect of ACTH on pure exocrine pancreatic secretion was studied in seven patients with external transduodenal drainage of the main pancreatic duct performed after biliary tract surgery. The i.v. injection of ACTH (0.25 mg) during a prolonged i.v. infusion of secretin (0.5 clinical U/kg/hr) plus cholecystokinin (0.5 Ivy dog U/kg/hr) significantly reduced both the concentration and output of lipase (peak -41% and -41%, resp.) and of protein (-39% and -36%, resp.) without affecting volum and bicarbonate secretion. The reduction appeared soon after ACTH injection (peak inhibition in the first 15-min period) and lasted about 75 min. The adrenocortical response to ACTH reached its peak at the 60th min. The mechanism by which the pituitary hormone selectively inhibits pancreatic enzyme secretion without affecting volume and bicarbonate remains to be clarified.

1853 THE DEPENDENCE OF CAERULEIN-EVOKED PANCREATIC FLUID SECRETION ON THE EXTRACELLULAR CALCIUM CONCENTRATION. (Eng.) Ueda, N.;

Petersen, O. H. (Asahikawa Univ. Sch. Medicine, Asahikawa, Hokkaido, Japan). *Pfluegers Arch.* 370 (2):179-183; 1977.

Fluid and amylase secretion was measured in the perfused rat pancreas in the absence of and during cerulein or secretin stimulation. The removal of Ca^{2+} from the perfusion fluid only slightly reduced spontaneous fluid secretion, but caused a marked reduction in the amylase output. In experiments in which the CO$_2$/HCO$_3^-$ buffer had been replaced by tris buffer, removal of Ca^{2+} abolished spontaneous fluid and amylase secretion. Elimination of Ca^{2+} during continuous stimulation with cerulein (10^{-10} M) caused an immediate rapid reduction in fluid and amylase secretion, which was reversible upon readmission of Ca^{2+}. Removal of perfusion fluid Ca^{2+} and addition of ethylene glycol bis(β-aminoethyl ether)*N,N*-tetraacetic acid during secretin stimulation had no effect on fluid for the first 30 min after the start of Ca^{2+} deprivation. Thereafter, a gradual reduction in fluid flow occurred, which was nonreversible upon Ca^{2+} readmission. During stimulation with monobutyryl cyclic AMP, Ca^{2+}-deprivation failed to reduce fluid secretion within a 30-min period. Increasing the concentration of Ca^{2+} in the perfusion fluid to 20 mM during stimulation with cerulein caused a sharp reduction in fluid secretion and a small decrease in amylase output. These effects were partially reversible if the period of exposure to the high Ca^{2+} concentration was less than 20 min. It is concluded that extracellular Ca^{2+} is important for cerulein-evoked, but not for secretin-evoked, fluid secretion.

1854 EFFECT OF EXTRACELLULAR K$^+$ CONCENTRATION ON RESTING POTENTIAL, CAERULEIN-INDUCED DEPOLARIZATION AND AMYLASE RELEASE FROM MOUSE PANCREATIC ACINAR CELLS.

(Eng.) Poulsen, J. H.; Williams, J. A. (Panum Inst., Univ. Copenhagen, Blegdamsvej 3-C, DK-2200 Copenhagen N, Denmark). *Pfluegers Arch.* 370(2):173-177; 1977.

Studies were carried out to investigate the possible role of stimulation-induced depolarization in pancreatic enzyme secretion. Acinar cell membrane potentials and amylase release were measured from *in vitro* preparations of mouse pancreas. The effect of a 10-fold increase of the extracellular K$^+$ concentration (to 47 mM) was studied on the resting membrane potential and amylase release, as well as on the membrane depolarization and amylase release induced by cerulein. In the presence of atropine (to exclude the effect of a possible release of endogenous acetylcholine), the increased K$^+$ concentration depolarized the cells from -45 to -20 mV without influencing the rate of the unstimulated release of amylase. Under these conditions, the depolarizing effect of cerulein was almost abolished, while the cerulein-induced amylase was not. It is concluded that cerulein-induced enzyme secretion from pancreatic acinar cells is independent of the level of the membrane potential, as well as extracellular K$^+$ concentration, in the range from 4.7 to 47 mM.

1855 SECRETION OF PANCREATIC JUICE IN RESPONSE TO NERVOUS AND HORMONAL STIMULATION IN THE ANAESTHETIZED MONKEY (Erhythrocebus patas AND Papio mandrillus).

(Eng.) Vega, D. F.; Martinez-Victoria, E.; Esteller, A.; Murillo, A. (Dept. Animal Physiology, Univ. Granada, Spain). *Comp. Biochem. Physiol.* [*A*] 58(3A):259-264; 1977.

Exocrine pancreatic secretion was studied in two primate species *(Erythrocebus patas* and *Papio mandrillus).* The resting flow in *P. mandrillus* was high (33.0-86.0 µl/min) and contained a low concentration of amylase (2.73-3.43 U/ml). There was no resting secretion in *E. patas.* The i.v. infusion of secretin increased the flow of pancreatic juice in a dose-related manner in both species, the monkeys being highly sensitive to the hormone. In *E. patas,* a single injection or infusions of cholecystokinin-pancreozymin increased the flow and amylase content of the juice. Stimulation of the cervical vagus nerves increased the flow and amylase content of the juice in both species; there were wide differences between individuals of the same species as well as between species. Atropine reduced, but did not abolish the pancreatic response caused by vagal stimulation. In *E. patas,* the concentration of chloride ions fell when the flow of juice increased; in *P. mandrillus* the concentration remained constant at different rates of flow. These experiments show that there may be substantial differences in the properties of the exocrine pancreas between related primate species.

1856 PANCREATIC DUCT CELLS IN RATS: SECRETORY STUDIES IN RESPONSE TO SECRETIN, CHOLECYSTOKININ-PANCREOZYMIN, AND GASTRIN IN VIVO.

(Eng.) Folsch, U. R.; Creutzfeldt, W. (Dept. Medicine, Univ. Gottingen, Humboldtallee 1, D-3400 Gottingen, W. Germany). *Gastroenterology* 73(5): 1053-1059; 1977.

The sensitivity and secretory pattern of pancreatic duct cells to a variety of hormones was investigated in male Wistar rats that received a copper-deficient diet supplemented with D-penicillamine (300 mg/kg/day) for 100 days, a regimen that selectively destroys acinar tissue. Resting flow rate of this pancreatic duct model was in the same range as that in the intact gland. The duct cells responded to increasing doses of secretin (2-60 clinical U/kg/hr, i.v.) by producing more juice with increasing outputs of bicarbonate, sodium, potassium, and chloride. Bicarbonate concentration increased with the lowest dose of secretin up to values of 64 mEq/l and did not further increase with higher doses of secretin and increasing secretory rates. The potassium concentration increased with increasing doses of secretin and flow rates, whereas chloride concentration decreased in a reciprocal fashion to bicarbonate. Gastrin (20 µg/kg/hr) and cholecystokinin-pancreozymin (60 Ivy dog U) did not significantly stimulate the duct cells. Atropine (150 µg/kg followed by 150 µg/kg/hr or 250 µg/kg followed by 250 µg/kg/hr) did not inhibit the action of secretin on the flow rate or on bicarbonate secretion.

1857 EFFECTS OF CHOLECYSTOKININ ON ADENYLATE CYCLASE ACTIVITY IN DISPERSED PANCREATIC ACINAR CELLS. (Eng.) Long, B. W.; Gardner, J. D. (Natl. Inst. Arthritis, Metabolism, and Digestive Diseases, Natl. Inst. Health, Bethesda, MD 20014). *Gastroenterology* 73(5):1008-1014; 1977.

Studies were carried out to determine whether the receptor through which cholecystokinin octapeptide (CCK-OP) increases calcium outflux and cellular cyclic guanosine monophosphate (GMP) in intact acinar cells is the same receptor through which CCK-OP increases adenylate cyclase activity in a broken cell system. In addition, the ability of CCK-OP to modify the effect of other peptides on cyclic AMP in intact acinar cells and on adenylate cyclase in homogenates of acinar cells was examined. In dispersed acinar cells prepared from guinea pig pancreas, secretin, and vasoactive intestinal peptide (VIP) but not CCK-OP or [^{32}alanine] (^{32}Ala)-CCK-OP increased cyclic AMP concentration. At concentrations above 10^{-5} M CCK-OP as well as the 32-alanine analogue inhibited noncompetitively the increase in cyclic AMP level caused by secretin or VIP. In homogenates of acinar cells secretin, VIP, and CCK-OP but not [^{32}Ala]CCK-OP increased adenylate cyclase activity. At concentrations below 10^{-5} M, [^{32}Ala]-CCK-OP potentiated the increase in adenylate cyclase activity caused by secretin or VIP. At concentrations above 10^{-5} M, CCK-OP and the 32-alanine analogue inhibited noncompetitively the increase in adenylate cyclase activity caused by secretin and VIP. Analogues and fragments of CCK-OP showed a pattern for increasing adenylate cyclase activity that differed from that for increasing calcium outflux from intact acinar cells. These findings suggest that, in addition to the class of receptors that mediate the effects of CCK-OP on calcium outflux and cyclic GMP, pancreatic acinar cells possess two additional classes of receptors via which CCK-OP alters adenylate cyclase activity. One of these two classes of receptors is accessible only in broken cell preparations and, when occupied by CCK-OP, increases adenylate cyclase activity, whereas, when occupied by the 32-alanine analogue, potentiates the effects of secretin or VIP on adenylate cyclase activity. The other class of receptors is accessible to CCK-OP or [^{32}Ala]CCK-OP in intact cells as well as in homogenates, and, when occupied by either of these two peptides, inhibits the stimulation of adenylate cyclase activity by secretin, VIP, or CCK-OP.

1858 EFFECT OF CHOLECYSTOKININ VARIANT (CCK$_{39}$) ON DISPERSED ACINAR CELLS FROM GUINEA PIG PANCREAS. (Eng.) Sjodin, L.; Gardner, J. D. (Dept. Pharmacology, Karolinska Institutet S-10401, Stockholm, Sweden). *Gastroenterology* 73 (5):1015-1018; 1977.

Dispersed pancreatic acinar cells of male Hartley guinea pigs were used to investigate the effects of cholecystokinin (CCK$_{33}$) and a peptide termed "cholecystokinin variant" (CCK$_{39}$) on calcium outflux, cyclic GMP, amylase release, and adenylate cyclase activity, and these effects were compared with those of cholecystokinin octapeptide (CCK-OP). CCK$_{39}$ and CCK$_{33}$ or CCK-OP caused significant increases in the outflux of ^{45}Ca, cyclic GMP, and amylase release. In homogenates of acinar cells, each peptide caused a significant increase in adenylate cyclase activity. For each function tested, CCK$_{39}$ was equipotent with CCK$_{33}$; CCK$_{39}$ and CCK$_{33}$ were 10 to 30 times less potent than CCK-OP. The efficacies of CCK$_{39}$, CCK$_{33}$, and CCK-OP were the same, and none of these effects were altered by a concentration of atropine (10^{-4} M) sufficient to abolish the action of muscarinic cholinergic agents.

1859 SIMULTANEOUS MEASUREMENT OF BASAL PANCREATIC, GASTRIC ACID SECRETION, PLASMA GASTRIN, AND SECRETIN DURING SMOKING. (Eng.) Murthy, S. N. S.; Dinoso, V. P., Jr.; Clearfield, H. R.; Chey, W. Y. (Hahnemann Medical Coll. and Hosp., 230 North Broad St., Philadelphia, PA 19102). *Gastroenterology* 73(4, Part 1):758-761; 1977.

The effect of smoking one unfiltered cigarette every 15 min for 1 hr on basal gastric acid and pancreatic secretion was studied in 10 subjects with a history of duodenal ulcer and 10 without duodenal ulcer. All ulcer patients and five controls were smokers. Smoking induced a transient rise of basal acid output followed by a slight decrease. This effect was more pronounced in the duodenal ulcer group ($p<0.05$). Smoking markedly inhibited fluid and bicarbonate secretion during the smoking period. The bicarbonate and fluid secretion returned to control levels within 30 to 60 min in the ulcer group and in 60 to 90 min in the nonulcer group. There was no difference in the degree of inhibition of pancreatic secretion between the two groups. Immunoreactive gastrin and secretin in the peripheral venous blood did not change significantly during smoking. The degree of inhibition of basal pancreatic secretion correlated well with the plasma concentrations of nicotine; the correlation coefficients at 15, 30, 45, and 60 min during the smoking period were 0.290, 0.864, 0.925, and 0.451, resp. These observations indicate that smoking in the fasting state induces alterations of basal gastric and pancreatic secretions that are not related to changes in plasma gastrin and secretin concentration, but to plasma concentrations of nicotine.

1860 CHARACTERISTICS OF INHIBITION OF PANCREATIC SECRETION BY ISOPROTERENOL. (Eng.) Kelly, G. A.; Rose, R. C.; Nahrwold, D. L. (Milton S. Hershey Medical Center, Hershey, PA 17033). *Surgery* 82(5):680-684; 1977.

The effect of isoproterenol on pancreatic secretion stimulated by the octapeptide of cholecystokinin (OP-CCK) was studied in dogs with gastric and pancreatic fistulas. Special precautions were taken to prevent entry of gastric acid into the duodenum and reflux of duodenal content into the stomach; a balloon seal prevented the entry of gastric contents into the duodenum and reflux of duodenal content into the stomach, and the effectiveness of the seal was confirmed by the injection of phenol red. The i.v. infusion of OP-CCK increased volume and the outputs of bicarbonate and protein from the pancreas. Isoproterenol produced a dose-related inhibition of pancreatic responses to OP-CCK. Propranolol blocked the inhibitory action of isoproterenol completely. Analysis of data by Michaelis-Menten kinetics revealed that there was competitive inhibition of protein output with noncompetitive inhibition of bicarbonate output. The experiments show that isoproterenol inhibits OP-CCK-stimulated pancreatic secretion by a beta-adrenergic mechanism. The kinetic analysis suggests that the intimate mechanisms involved in inhibition of protein and bicarbonate output by isoproterenol are different.

1861 ACTION OF OLEIC ACID ON THE EXOCRINE PANCREATIC SECRETION OF THE CONSCIOUS RAT: EVIDENCE FOR AN ANTI-CHOLECYSTOKININ-PANCREOZYMIN FACTOR. (Eng.) Laugier, R.; Sarles, H. (INSERM U 31, 46 chemin de la Gaye, 13009 Marseille, France). *J. Physiol. (Lond.)* 271(1):81-92; 1977.

The effects of an intraduodenal infusion of oleic acid (2 ml in 60 min) on pancreatic secretion were assessed in conscious rats provided with a new type of duodenal cannula permitting the normal flow of pancreatic juice, but not of bile, between experiments. Intraduodenal oleic acid infusion induced increased water and bicarbonate secretion, which was still significantly above basal values 90 min after the end of the infusion. Protein output increased during the infusion, but protein concentration and output significantly decreased under basal levels 120 min and 150 min after infusion (-63 and -57% of basal values at 150 min, resp.). No inhibition was found when oleic acid was introduced into the cecum or into the first 20 cm of ileum isolated from the rest of small intestine. On the contrary, inhibition of protein secretion was induced immediately by intraileal oleic acid infusion. Inhibition of protein secretion secondary to intra-ileal oleic acid infusion was transmitted from a donor rat to a receiver rat by means of a cross-circulation. It is concluded that oleic acid induces an immediate and long lasting increase in water and bicarbonate secretion. During the infusion of oleic acid, protein output is increased, followed by inhibition. This delayed inhibition stems from the second part of the small intestine and was transferred from one rat to another by cross-circulation; it is speculated that oleic acid releases in the conscious rat (from the distal part of the small intestine) a hormonal factor inhibiting pancreatic secretion.

1862 EFFECT OF FASTING AND REFEEDING ON PANCREATIC DNA SYNTHESIS AND CONTENT. (Eng.) Mainz, D. L.; Parks, N. M.; Webster, P. D., III (Veterans Admin. Hosp., Augusta, GA 30904). *Proc. Soc. Exp. Biol. Med.* 156(2):340-344; 1977.

The effects of fasting and refeeding on pancreatic DNA content and rates of [^{14}C]thymidine incorporation into DNA were examined in male Sprague-Dawley rats. After fasting for 2, 4, and 6 days or fasting for 6 days with refeeding for 1, 2, and 3 days, pancreatic weight decreased 8%, 28%, and 43%, resp., and then increased 23%, 12%, and 36%, resp.; DNA content decreased 2%, 9%, and 20%, resp., and then increased 6%, 4%, and 16%, resp. [^{14}C]thymidine incorporation into DNA decreased 40%, 69%, and 86%, resp., and then increased 70%, 267%, and 511%, resp. These studies show the influence of fasting and refeeding on rates of pancreatic DNA synthesis and on DNA content. Control studies demonstrated similar decreases in kidneys, muscle, and spleen. These changes represent complex metabolic adaptive responses to food deprivation. The changes may be mediated in part by lack of substrate but probably also reflect alterations in the hormonal milieu.

1863 EFFECT OF FEEDING SOYBEAN FLOUR CONTAINING DIETS ON THE PROTEIN SYNTHETIC PATTERN OF THE RAT PANCREAS. (Eng.) Dijkhof, J.; Poort, S. R.; Poort, C. (Medical Sch., State Univ., Utrecht, 2501, 22 Nicolaas Beetsstraat, Netherlands). *J. Nutr.* 107(11):1985-1995; 1977.

The influence of p.o.-ingested diets containing raw soybean flour (RSD) as compared to heated soybean flour (HSD) on the *in vitro* synthesis of rat pancreatic secretory proteins was determined using a new method that avoids the determination of enzymic activity. After a 5-day feeding period, half of the pancreas is incubated with [^{3}H]leucine as the precursor, whereas the other half is presented with [^{14}C]leucine. Extracts are prepared from both pancreas halves, mixed, and the extract mixture is subjected to polyacrylamide gel electrophoresis. The ^{3}H/^{14}C ratio of disintegrations/min is determined in each 1-mm slice of the gel. Using this double-label method, it is possible to circumvent the determination of enzymic activity and of specific radioactivity per enzyme. Any change in the rate of synthesis of a protein is recorded as a deviation in the ^{3}H/^{14}C ratio from the total ratio between the two isotopes in trichloroacetic acid-insoluble material. Three amylases, three trypsinogens, two chymotrypsinogens, lipase, ribonuclease, and proelastase were localized in the gel. In RSD-fed rats, all amylase isoenzymes were synthesized at a lower rate than in the HSD-fed rats, whereas the synthesis of two trypsinogens and of one chymotrypsinogen were increased. The synthesis of the second chymotrypsinogen was slightly lowered, and ribonuclease, proelastase, and one trypsinogen were unaffected in their synthetic rates.

1864 RELATIONSHIPS BETWEEN FASTING AND POSTPRANDIAL PANCREATICODUODENAL PRESSURES, PANCREATIC SECRETION, AND DUODENAL VOLUME FLOW IN THE DOG. (Eng.) Owyang, C.; Dozois, R. R.; DiMagno, E. P.; Go, V. L. W. (Mayo Clinic and Mayo Foundation, Rochester, MN 55901). *Gastroenterology* 73(5):1046-1049; 1977.

A canine model that allows simultaneous quantification of pancreatic enzyme outputs, duodenal volume flow, and pancreatic and duodenal pressures under physiological circumstances was developed to determine whether pancreaticoduodenal pressure relationships exist that may permit reflux into the pancreatic duct. Twelve studies on four conscious healthy dogs demonstrated that mean fasting pancreatic pressure was 5 to 10 cm H_2O higher than mean fasting duodenal pressure. Furthermore, 8 min after ingestion of a meal, both the pancreatic and the duodenal pressure increased. Surprisingly, the mean duodenal pressure was higher than the mean pancreatic pressure 20 min after feeding. This relationship lasted for 30 min. Elevation of postprandial pancreatic pressure occurred concomitantly with increased pancreatic enzyme output, and duodenal pressure increased with increased duodenal volume flow. The large postprandial duodenal volume flows associated with duodenal pressures greater than pancreatic duct pressures may favor reflux of duodenal contents into the pancreatic duct. These relationships may be important in the pathogenesis of postprandial pancreatitis and in the induction of pancreatic cancer.

1865 EXPERIMENTAL STUDY ON TRANSDUCTAL DISSEMINATION OF CANCER OF THE PANCREAS. (Eng.) Fujita, N.; Nakase, A. (Kyoto Univ. Medical Sch., Shogoin Kawaramachi 45, Sakyo-ku, Kyoto, 606 Japan). *Gastroenterol. Jpn.* 12(3):224-229; 1977.

The mechanism of transductal dissemination of pancreatic carcinoma was studied in the rabbit by injecting a V_{x2} carcinoma suspension into the pancreatic duct. Ductal occlusion was conducive to implantation and growth in the pancreas of intraductal floating cancer cells, and tumors occurred in all rabbits with occlusion. Tumor growth also occurred in 40% of animals in which the duct was not occluded. Implantation of intraductal floating cancer cells took place by direct embedding into the ductal wall and by leakage of cancer cells from the duct in the process of pancreatic fibrosis due to ductal obstruction. Expansive tumor growth in the pancreas was more vigorous in pancreas with less fibrosis and was most active with concomitant acute pancreatitis or where the pancreas was x-irradiated (1,000-1,250 rads) 1 week before injection of the carcinoma suspension.

1866 STIMULUS-SECRETION COUPLING IN THE EXOCRINE PANCREAS: STUDIES WITH VINBLASTINE, DEUTERIUM OXIDE AND CYTOCHALASIN B [Abstract]. (Eng.) Stock, C.; Launay, J. F.; Bauduin, H.; Grenier, J. F. *Ir. J. Med. Sci.* 146(Suppl. 1):19-20; 1977.

1867 EFFECT OF ENKEPHALIN AND MORPHINE ON HORMONES STIMULATING EXOCRINE PANCREATIC SECRETION [Abstract]. (Eng.) Konturek, S. J.; Tasler, J.; Cieszkowski, M.; Jaworek, J. (Inst. Physiology, Medical Acad., Cracow, Poland). *Ir. J. Med. Sci.* 146(Suppl. 1):14-15; 1977.

1868 PHYSIOLOGICAL ROLE OF PP IN MAN [Abstract]. (Eng.) Bloom, S. R.; Greenberg, G. R.; Adrian, T. E.; Besterman, H. S.; Mallinson, C. N.; McCloy, R. F.; *et al.* (Hammersmith Hosp., London W12, England). *Ir. J. Med. Sci.* 146(Suppl. 1):15; 1977.

1869 PANCREATIC EFFECTS OF A PARTIALLY PURIFIED DUODENAL SOMATOSTATIN-LIKE IMMUNOREACTIVE PEPTIDE (S.L.I.) [Abstract]. (Eng.) Susini, C.; Pradayrol, L.; Bommelaer, G.; Esteve, J. SECRETION AND METABOLISM

Hepatobiliary Tract

1879 PREPARATION OF PARENCHYMAL AND NON-PARENCHYMAL CELLS FROM ADULT HUMAN LIVER--MORPHOLOGICAL AND BIOCHEMICAL CHARACTERISTICS. (Eng.) Bojar, H.; Basler, M.; Fuchs, F.; Dreyfurst, R.; Staib, W. (Institut fur Physiologische Chemie II der Universitat Dusseldorf, Moorenstrasse 5, 4000 Dusseldorf, W. Germany). *J. Clin. Chem. Clin. Biochem.* 14(11):527-532; 1976.

A method for the preparation and separation of isolated human liver cells into pure parenchymal and nonparenchymal cell suspensions is described, and the cells are briefly characterized. A mixed suspension of various cell types was obtained by perfusing the isolated human liver with collagenase and hyaluronidase. Pure parenchymal cells are prepared by differential centrifugation, pure nonparenchymal cells by the use of pronase and subsequent isopycnic centrifugation on metrizamide gradients (50-300 g/l). About 90% of the parenchymal and nonparenchymal cells were viable as judged by trypan blue staining. Nonparenchymal cells were not capable of gluconeogenesis but utilized glucose at high rates. Parenchymal cells retained their ability to form glucose and to accumulate glycogen from fructose; glycogen was also synthesized, but to a lesser extent, when lactate or alanine were used as substrate. Studies on binding of ^{125}I-labeled insulin by isolated parenchymal cells were performed at 30 C. The binding data may fit a model with a minimum of two classes of binding sites: (a) high affinity-low capacity sites (dissociation constant [K_d] ∿6.6 nM, capacity ∿16,000 insulin molecules/cell) and (b) low affinity-high capacity sites (K_d ∿0.37 μM, capacity ∿646,000 molecules/cell).

1880 THE BILE ACID COMPOSITION OF RABBIT AND CAT GALL-BLADDER BILE. (Eng.) Taylor, W. (Medical Sch., Univ. Newcastle upon Tyne, Newcastle upon Tyne NE1 7RU, England). *J. Steroid Biochem.* 8(10):1077-1084; 1977.

Nonsulfated and sulfated bile acids from gallbladder bile of rabbits and cats were analyzed by gas chromatography-mass spectrometry. In the nonsulfated fraction of rabbit bile, deoxycholic acid was the predominant bile acid. The sulfate fraction (B.A.S.) contained lithocholic acid and small amounts of deoxycholic acid, allodeoxycholic acid, and their 3- and 12-epimers. No sex difference in the composition of rabbit bile was found. The nonsulfated fraction of cat bile contained the normal primary and secondary bile acids, with smaller amounts of other bile acids. The B.A.S. fraction contained isomers of cholic and deoxycholic acids; allodeoxycholic and lithocholic acids predominated. The pattern of bile acids in the B.A.S. fraction of cat bile was much more complex than that of rabbit bile. An important feature of the cat bile B.A.S. fraction was the very small amount of cholic acid present. Male cats produced about twice as much B.A.S. as did female cats, but the females produced more nonsulfated bile acids than the males.

1881 EFFECTS OF CHLORPROMAZINE HYDROCHLORIDE ON BILE FLOW, BILE SALT SYNTHESIS AND BILIARY LIPID SECRETION IN THE PRIMATE. (Eng.) Ros, E.; Small, D. M.; Carey, M. C. *In: Bile Acid Metabolism in Health and Disease. Proceedings of the IV Bile Acid Meeting held at the Hilton Hotel, Basel, Switzerland, October 11-12, 1976.* University Park Press (Baltimore, MD): 219-227; 1977.

The effects of i.v. infusions of chlorpromazine hydrochloride (2.5-10.0 mg/kg) on bile formation were investigated in the bile fistula rhesus monkey during stimulation of the enterohepatic circulation with a constant infusion of [^{14}C]sodium taurocholate. Chlorpromazine reversibly inhibited bile salt-independent flow and biliary lipid secretion. During cholestasis, extrahepatic retention of bile salt occurred, and endogenous bile salt synthesis was impaired either due to the drug itself or its metabolites or to the retained bile salts. These studies indicate that, in the rhesus monkey, chlorpromazine cholestasis is not prevented by simulation of an intact enterohepatic circulation.

1882 HEPATIC UPTAKE, STORAGE AND BILIARY TRANSPORT MAXIMUM OF BILE ACIDS IN THE DOG. (Eng.) Erlinger, S.; Poupon, R.; Glasinovic, J. C.; Dumont, M. *In: Bile Acid Metabolism in Health and Disease. Proceedings of the IV Bile Acid Meeting held at the Hilton Hotel, Basel, Switzerland, October 11-12, 1976.* University Park Press (Baltimore, MD): 107-112; 1977.

The hepatic uptake of taurocholate was estimated in anesthetized dogs using a multiple-indicator dilution method. The nonlinear increase of the velocity of uptake of taurocholate with the dose was consistent with saturation kinetics. The increase in the half-saturation constant of taurocholate upon the addition of taurochenodeoxycholate was consistent with competitive inhibition of taurocholate uptake by taurochenodeoxycholate. This result suggests the existence of a carrier-mediated transport system for the uptake of bile acids. Intracellular storage and biliary transport maximum were assessed by a multiple-infusion method. A relative storage capacity was measured for both taurocholate and taurochenodeoxycholate, suggesting a storage phenomenon for bile acids. Biliary transport maximum, estimated by the same method, was 6-10 times lower than the maximal initial velocity of uptake. These studies indicate that, in the overall process of hepatic transport, excretion may be the limiting step and intracellular storage may occur.

1883 SEX DIFFERENCES IN SULFATION AND EXCRETION OF 5α-CHOLANOIC ACIDS IN RATS. (Eng.) Eriksson, H.; Taylor, W.; Sjovall, J. *In: Bile Acid Metabolism in Health and Disease. Proceedings of the IV Bile Acid Meeting Held at the Hilton Hotel, Basel, Switzerland, October 11-12, 1976.* University Park Press (Baltimore, MD): 75-81; 1977.

In order to study sex differences in the sulfation and excretion of 5α-cholanoic acids in rats, bile acids in bile from male and female rats were analyzed by ion exchange chromatography and repetitive scanning gas chromatography-mass spectrometry. Female rats excreted 5 to 10 times more sulfated bile acids than male rats. Most sulfated bile acids had a 5α-configuration and allochenodeoxycholic acid was the major compound, excreted only by female rats. The main part of allochenodeoxycholic acid may arise via microsomal 5α-reduction, whereas dietary cholestanol may be the major precursor of allocholic acid.

1884 EXCRETION OF TAUROCHOLATE FROM ISOLATED HEPATOCYTES. (Eng.) Schwarz, L. R.; Schwenk, M.; Pfaff, E.; Greim, H. (Abteilung fur Toxikologie, Gesellschaft fur Strahlen- und Umweltforschung mbH, Ingolstadter Landstrasse 1, D-8042 Neuherberg, W. Germany). *Eur. J. Biochem.* 71(2):369-373; 1976.

Efflux of taurocholate from isolated rat hepatocytes was studied to characterize the mechanism of bile acid secretion and to investigate whether isolated hepatocytes are suitable to study bile acid secretion. Cells from male Sprague-Dawley rats were incubated with taurocholate for 15 min. The amount of the intracellularly accumulated bile acid was directly related to the concentration in the medium (5-100 μM). Transfer of the loaded cells from the incubation medium to a medium without taurocholate led to taurocholate efflux. Efflux was saturable, and its activation energy amounted to 12 kcal/mol. It was almost completely inhibited by 5 μg/ml antimycin A and by 23% by the uncoupler carbonyl cyanide-*m*-chlorophenylhydrazone (2 μM). Dinitrofluorobenzene and mersalyl, reagents that react with amino acids, inhibited efflux by about 30% when applied at concentrations of 50 μM. Ouabain (1 mM) increased the rate of efflux. The observations indicate that secretory functions are maintained in isolated liver cells.

1885 EFFECTS OF CHOLESTATIC STEROIDS ON UPTAKE AND RELEASE OF TAUROCHOLATE IN ISOLATED HEPATOCYTES. (Eng.) Schwarz, L. R.; Schwenk, M.; Greim, H. *In: Bile Acid Metabolism in Health and Disease. Proceedings of the IV Bile Acid Meeting held at the Hilton Hotel, Basel, Switzerland, October 11-12, 1976.* University Park Press (Baltimore, MD): 145-150; 1977.

Uptake and efflux of taurocholate were studied in isolated liver cells. Both processes were found to be saturable, energy dependent, and susceptible to protein reagents. Norethandrolone (500 μM), 17-β estradiol (50 μM), and progesterone (50 μM) inhibited taurocholate uptake into hepatocytes. Norethandrolone decreased efflux of the bile acid only at the very high concentration of 500 μM. Thus, inhibition of taurocholate uptake may be involved in the pathogenesis of steroid-induced intrahepatic cholestasis

1886 ACCELERATED HEPATIC HAEM CATABOLISM IN THE SELENIUM-DEFICIENT RAT. (Eng.) Burk, R. F.; Correia, M. A. (Univ. Texas Health Science Center, Dallas, TX 75235). *Biochem. J.* 168(1):105-111; 1977.

The heme anabolism and catabolism were studied in phenobarbital-treated, selenium-deficient rats; in addition, apo-(cytochrome P-450) synthesis was investigated in these rats. Hepatic microsomal cytochrome P-450 concentrations were lower in selenium-deficient rats treated with phenobarbital (80 mg/kg, i.p.) for 4 days than in similarly treated controls. No defect in heme synthesis was found on the basis of measurements of δ-aminolevulinate synthase; δ-aminolevulinate dehydratase and ferrochelatase activities; and urinary excretion of δ-aminolevulinate, porphobilinogen, uroporphyrin, and coproporphyrin. No defect in apo-(cytochrome P-450) synthesis was found by studies of [^{3}H]- and [^{14}C]leucine incorporation into apo-(cytochrome P-450) separated by sodium dodecyl sulfate/polyacrylamide-gel electrophoresis. An increase in heme catabolism was found. An eightfold increase in hepatic microsomal heme oxygenase activity occurred in selenium-deficient rats after phenobarbital treatment, compared with a less than twofold increase in control rats. Breath ^{14}CO excretion after administration of δ-amino[5-^{14}C]levulinate was greater by phenobarbital-treated selenium-deficient rats than by similarly treated controls. These studies demonstrate that the defective induction of cytochrome P-450 by phenobarbital in selenium-deficient rats is accompanied by increased heme catabolism, which could be due to increased breakdown of cytochrome P-450 or to catabolism of heme before it attaches to the apo-cytochrome. The role of selenium in stabilizing cytochrome P-450 and/or in protecting heme from breakdown remains to be determined.

1887 THE TRANSFER OF ESTRONE GLUCURONIDE TO BILE IN AN ISOLATED PERFUSED RAT LIVER SYSTEM.

(Eng.) Watanabe, H. (Drug Res. Lab., Ottawa, Ontario K1A OL2, Canada). *Steroids* 29(6): 837-848; 1977.

In an effort to establish a system for the study of biliary estrogen excretion, an isolated rat liver perfusion system was used in a study of the biliary excretion of estrone glucuronide. The estrogen was previously shown to be excreted without prior metabolism. Disappearance from the medium was rapid, and biliary concentrations exceeded that in the medium by more than a 1,000-fold. Disappearance rates were decreased when the estrone glucuronide concentrations in the medium exceeded 0.29 mM. Inhibition by other steroidal conjugates, testosterone glucuronide, 2-methoxyesterone (3-hydroxy-2-methoxy-estra-1,3,5(10)-trien-17-one) glucuronide, and 2-hydroxyestrone (2,3-dihydroxyestra-1,3,5(10)-trien-17-one) glutathione, was also demonstrated. Phenolphthalein glucuronide, at 10 times the molar concentration of estrone glucuronide, did not affect the medium clearance of the latter compound. These findings indicate the possibility of utilizing this system for further studies of possible interactions by other organic compounds for biliary excretion.

1888 REGULATION OF UREA SYNTHESIS IN RAT LIVER. CHANGES OF ORNITHINE AND ACETYLGLUTAMATE CONCENTRATIONS IN THE LIVERS OF RATS SUBJECTED TO DIETARY TRANSITIONS.

(Eng.) Saheki, T.; Katsunuma, T.; Sase, M. (Sch. Medicine, Tokai Univ., Bohseidai, Isehara, Kanagawa 259-11, Japan). *J. Biochem. (Tokyo)* 82(2):551-558; 1977.

Regulation of urea synthesis *in vivo* was studied in rats subjected to acute dietary transitions from a 70% to a 5% casein diet or *vice versa*. A 700% increase in urea excretion and a significant increase in urea level in the liver preceded an increase in argininosuccinate synthetase activity when the casein level was increased, and significant decreases in these levels were seen when the casein level was decreased. Immunochemical determination of argininosuccinate synthetase showed that the increase/decrease of the enzyme activity was directly related to the actual increase/decrease of the amount of enzyme protein. The ratios of the initial velocity of urea synthesis from ammonium chloride to the enzymatic activity of argininosuccinate synthetase in the perfused livers were determined. Shortly after the switch of casein diet from 70% to 5%, the ratios decreased to much lower values than those of rats fed on the 5% casein diet for 7 days, while, during the acute transition from 5% to 70% casein diet, the ratios increased above the values of rats fed on the 70% casein diet for 7 days. The concentrations of ornithine and acetylglutamate capable of stimulating urea synthesis changed significantly shortly after the dietary switch. The concentration of ornithine overshot the steady-state level of rats fed on 70% casein after the dietary switch from 5% to 70% casein. Ornithine concentration declined rapidly after the dietary switch from 70% to 5%, falling below the steady-state level of rats fed on the 5% casein diet. Thus, in both cases, new steady-state levels of ornithine concentration were established. The findings that fluctuations of ornithine and acetylglutamate concentration were greater and occurred prior to the activity changes of argininosuccinate synthetase strongly suggest a possible regulatory function of these amino acids in urea synthesis.

1889 OXYGEN GRADIENTS DURING HYPOXIC STEADY STATES IN LIVER. URATE OXIDASE AND CYTOCHROME OXIDASE AS INTRACELLULAR O_2 INDICATORS.

(Eng.) Sies, H. (Institut fur Physiologische Chemie, Physikalische Biochemie und Zellbiologie der Universitat Munchen, Goethestrasse 33, D-8000 Munchen 2, W. Germany). *Hoppe Seylers Z. Physiol. Chem.* 358(8):1021-1032; 1977.

Urate oxidase and cytochrome oxidase were assayed in a study of intercellular O_2 gradients in hypoxic steady states in the isolated perfused liver and isolated hepatocytes of male Wistar rats. An O_2 concentration of 1.0 mM in the influent resulted in a cytochrome oxidase reduction of 0% and a 100% rate of urate removal by the liver (274 nmol/min/g liver). Urate removal in the isolated hepatocytes was 528 nmol/min/g hepatocytes. In the hypoxic steady state in the hepatocytes, there was a 90% restriction of urate removal with only a 10% reduction of cytochrome oxidase. These results show a similar dependence of urate oxidase and cytochrome oxidase on O_2 concentration in the perfused liver. The observed differences of O_2 dependence between the intact liver and the isolated hepatocytes suggest that in hypoxic steady states of the intact perfused liver, areas of high and low O_2 concentrations coexist.

1890 RECONSTITUTION OF THE MICROSOMAL ETHANOL-OXIDIZING SYSTEM: QUALITATIVE AND QUANTITATIVE CHANGES OF CYTOCHROME P-450 AFTER CHRONIC ETHANOL CONSUMPTION. (Eng.) Ohnishi, K.; Lieber, C. S. (Bronx Veterans Admin. Hosp., Bronx, NY). *J. Biol. Chem.* 252(20):7124-7131; 1977.

An ethanol-oxidizing system was reconstituted with cytochrome P-450, NADPH-cytochrome c reductase, and phospholipid. This system also metabolized propanol, butanol, and benzphetamine. Chronic ethanol feeding of either male or female rats for 4 to 12 weeks resulted in significant quantitative and qualitative changes in hepatic cytochrome P-450. The absorption maximum of CO-difference spectrum of cytochrome P-450 shifted to higher wavelength. Three hemoproteins were resolved by continuous buffer sodium dodecyl sulfate-polyacrylamide gel electrophoresis of rat liver microsomes. Two of these increased after chronic ethanol feeding. One of these hemoproteins was seen to be distinct from those induced by phenobarbital or 3-methylcholanthrene treatment. On discontinuous buffer sodium dodecyl sulfate-polyacrylamide gel electrophoresis there was a preferential increase of two proteins with apparent molecular weights of 53,400 and 52,000, resp. These two proteins probably represent the apoproteins of the two hemoproteins increased after chronic ethanol feeding. The partially purified cytochrome P-450 from ethanol-fed rats was more active for alcohol (ethanol, propanol, butanol) oxidation than was the control preparation in the presence of excess NADPH-cytochrome c reductase and L-α-dioleoyl lecithin. There was no significant difference in the capacity of partially purified NADPH-cytochrome c reductase from either ethanol-fed rats or controls to promote alcohol oxidation in the presence of cytochrome P-450 and L-α-dioleoyl lecithin. Thus, the adaptive increase of the microsomal ethanol-oxidizing system activity after chronic ethanol consumption can be attributed, at least in part, to quantitative and qualitative changes of cytochrome P-450.

1891 EFFECTS OF PROTEIN DEFICIENCY AND EXCESS ON HEPATIC MIXED FUNCTION OXIDASE ACTIVITY IN GROWING AND ADULT FEMALE RATS. (Eng.) Clinton, S. K.; Truex, C. R.; Visek, W. J. (Sch. Basic Medical Sciences, Univ. Illinois, Urbana, IL 61801). *Nutr. Rep. Int.* 16(4):463-470; 1977.

The effects of protein deficiency and excess on hepatic mixed function oxidase activity were studied in weanling and adult female Sprague-Dawley rats fed diets containing 7.5%, 15%, or 45% protein. Differences in body weight, liver lipids, and liver proteins were observed in rats fed experimental diets for 1 month but not 8 months. Increasing levels of cytochrome P-450, cytochrome b_5, and aniline hydroxylase were observed as dietary protein increased in both weanlings and adults; the cytochrome P-450 levels were 14.0 ± 1.0, 18.0 ± 3.0, and 24.0 ± 3.0 nmol/100 mg protein in rats fed 7.5%, 15%, and 45% protein for 8 months after weaning, resp., and 2.0 ± 0.6, 6.0 ± 0.3, and 9.0 ± 1.4 nmol/100 mg in those fed the respective diets for 1 month after weaning. The respective cytochrome b_5 levels in the rats fed for 8 months were 50.0 ± 4.0, 60.0 ± 10, and 74.0 ± 7 nmol/100 mg protein; in the rats fed for 1 month, the levels were 6.0 ± 1.0, 11.0 ± 1.0, and 17.0 ± 2 nmol/100 mg, resp. The aniline hydroxylase levels were 1.30 ± 0.08, 1.88 ± 0.08, and 2.18 ± 0.17 nmol *p*-aminophenol produced per 20 min/mg microsomal protein in the rats fed for 8 months and 0.45 ± 0.11, 0.66 ± 0.03, and 1.30 ± 0.08 nmol *p*-aminophenol produced per 20 min/mg microsomal protein in those fed for 1 month. The rats were able to compensate for the dietary-induced changes in liver composition and weight gain seen after 1 month; however, differences in mixed function oxidase activity were still evident in adults. The data show that alterations in mixed function oxidase activity are produced by protein excess as well as protein deficiency.

1892 HEPATIC OXIDATIVE DRUG METABOLISM IN RATS WITH EXPERIMENTAL RENAL FAILURE. (Eng.) Van Peer, A. P.; Belpaire, F. M. (Univ. Ghent Medical Sch., De Pintelaan 135, B-9000 Ghent, Belgium). *Arch. Int. Pharmacodyn. Ther.* 228(2):180-183; 1977.

To investigate the shortened half-life of drugs eliminated by the liver that is observed in renal failure in man, the activity of the drug-oxidizing system was studied in liver homogenates from control and uremic rats. Acute renal failure was achieved by ligation of the ureters or by the i.v. injection of urnayl nitrate. In the uremic state, the concentration of cytochrome P-450 and the activity of aniline hydroxylase were not significantly changed, but the activity of aminopyrine *N*-demethylase was significantly decreased (ureter ligation: 34.8 ± 2.6 versus 25.4 ± 2.9 nmol aminopyrine transformed/g liver/min, $p<0.05$; uranyl nitrate injection: 45.1 ± 2.3 versus 34.0 ± 1.8 nmol/g/min, $p<0.01$). In rats the hepatic oxidizing enzymes are not induced by uremia, in contrast to what has been suggested in man.

1893 GLUTATHIONE PEROXIDASE SYSTEM AND MICROSOMAL LIPOPEROXIDATION IN PRENECROTIC STAGES OF DIETARY HEPATIC NECROSIS IN RATS. (Eng.) Porta, E. A.; Ching, B. K. F.; Joun, N. S. (John A. Burns Sch. Medicine, Univ. Hawaii, Honolulu, HI 96822). *J. Nutr.* 107(10):1852-1858; 1977.

The possible relation between the state of the hepatic cytosol glutathione peroxidase (GSH-Px) system (including glutathione reductase, GSH-Rd, and glucose 6-phosphate dehydrogenase, G-6-PD) and hepatic microsomal lipoperoxidation (MLP) was investigated in male Wistar rats. In addition, to study the possible implications of these factors in the development of hepatic necrosis, weanling male rats were fed a basal diet low in Se and vitamin E or were pair-fed with the same diet supplemented with either *dl*-α-tocopherol (3 mg/100 g diet), sodium selenite (0.36 mg/100 g diet), or both. Rats from the four groups were killed at 9, 20, and 26 days. At the prenecrotic stage, GSH-Px activity in rats fed the basal diet alone was reduced by 97%, and the *in vitro* MLP levels (malonaldehyde) were increased by sevenfold as compared with rats fed the diet supplemented with Se and vitamin E. However, *in vivo* MLP (diene conjugation) was only detected in the liver of one rat that already had foci of necrosis at the time of killing. The decrease in GSH-Px was completely prevented by Se, but vitamin E had no effect. Dietary vitamin E and/or Se had little effect on the activity of GSH-Rd, but both agents, singly or in combination, prevented the reduction of G-6-PD that occurred in rats deficient in vitamin E and Se. The increased *in vitro* MLP was only partially reduced by either Se or vitamin E, since in both cases there still were threefold increases. These results suggest that (a) no clear-cut relation exists between the massive decline of cytosol GSH-Px and the development of hepatic necrosis, (b) the state of GSH-Px is probably unrelated to MLP, and (c) microsomes may not be the initial site of damage.

1894 ISOLATION OF II-ALCOHOL DEHYDROGENASE OF HUMAN LIVER: IS IT A DETERMINANT OF ALCOHOLISM? (Eng.) Li, T. K.; Bosron, W. F.; Dafeldecker, W. P.; Lange, L. G.; Vallee, B. L. (Indiana Univ. Sch. Medicine, Indianapolis, IN 46202). *Proc. Natl. Acad. Sci.* 74(10):4378-4381; 1977.

A functionally distinct, pyrrazole-insensitive form of human liver alcohol dehydrogenase (ADH), designated II-ADH, was isolated from human livers by affinity chromatography on 4-[3-(*N*-6-aminocaproyl) aminopropyl]-pyrazole-Sepharose, and its use as a determinant of alcoholism was investigated. II-ADH was found to be remarkably insensitive (apparent inhibition constant, K_I=500 μM) to pyrazole and its derivatives, which are usually potent ADH inhibitors (K_I=1 μM). This insensitivity of II-ADH to pyrazole inhibition permitted quantitation of its role in hepatic ethanol oxidation. At 5 mM ethanol, a saturating concentration for virtually all other forms of ADH, II-ADH contributed less than 15% to total ethanol oxidation. However, at intoxicating concentrations (60 mM), it accounted for as much as 40% of the total ethanol oxidation rate of liver, indicating a seemingly unique role for this enzyme form in ethanol elimination. The amount of II-ADH was found to vary from liver to liver of individuals and to be considerably more labile than the other molecular forms, phenomena whose inter- or independence requires further study. The isolation of human II-ADH advances efforts to recognize and understand biochemical mechanisms that may be biological determinants of alcoholism and alcohol-related disease states.

1895 TRITIUM EFFECT IN PEROXIDATION OF ETHANOL BY LIVER CATALASE. (Eng.) Damgaard, S. E. (Dept. Biochemistry A, Panum Inst., Univ. Copenhagen, DK-2200 Copenhagen, Denmark). *Biochem. J.* 167(1):77-86; 1977.

The ^3H isotope effect was calculated by the simultaneous determination of the rate of appearance of ^3H in water from [(1*R*-)-1-$^3H_1$]ethanol and the rate of acetaldehyde formation in the presence of rat- or ox liver catalase under conditions of steady-state generation of H_2O_2. The mean value of 2.52 obtained for rat-liver catalase at 37 C and pH 6.3-7.7 was independent of both ethanol concentration and the rate of H_2O_2 generation over a wide range. At 25 C, a slightly lower mean value of 2.40 was obtained with the ox liver catalase. Neither the product, acetaldehyde, nor 4-methylpyrazole influenced the two rates measured in the assay. Relating the value obtained for the ^3H isotope effect to a known value for the ^3H isotope effect strongly supported the view that both values are close to the true isotope effect with the respective substituted compounds on the rate constant in the catalytic step involving scission of the C-H bond. The constancy of the isotope effect under various conditions makes it possible to use it for interpretations *in vivo*. It was established that β-D-galactose dehydrogenase exhibits B-specificity towards the nicotinamide ring in NAD.

1896 EVIDENCE FOR CARBON TETRACHLORIDE- AND ETHANOL-INDUCED LIPID PEROXIDATION IN VIVO DEMONSTRATED BY ETHANE PRODUCTION IN MICE AND RATS. (Eng.) Koster, U.; Albrecht, D.; Kappus, H. (Inst. Toxicology, Univ. Tubingen, D 7400 Tubingen, W. Germany). *Toxicol. Appl. Pharmacol.* 41(3):639-648; 1977.

Experiments were carried out in mice and rats to determine whether carbon tetrachloride or ethanol induces lipid peroxidation. Mice and rats received carbon tetrachloride (1 g/kg) i.p. and were placed in a gas-tight all-glass desiccator connected to a gasometer containing pure oxygen. At different times gas samples from the dessicator were examined for their ethane content. Mice produced about 75 nmol of ethane/kg during 4 hr, whereas rats exhaled 45 nmol/kg during this time period. Control mice and rats produced only small amounts of ethane. Rats pretreated chronically with carbon tetrachloride (0.4 g/kg/day) for 6 weeks produced only about 21 nmol of ethane/kg during the 4 hr following an acute dose of carbon tetrachloride (1 g/kg). After rats were treated with ethanol (5 g/kg), they exhaled about 17 nmol of ethane/kg during 4 hr. The experiments demonstrate that, qualitatively, rats and mice do not differ in ethane production after carbon tetrachloride treatment. However, quantitatively, there are species variations. The results support the suggestion that acute doses of ethanol can induce lipid peroxidation *in vivo*.

1897 URINARY EXCRETION OF ALPHA-FETOPROTEIN IN RATS ON A CIRRHOGENIC CARBON TETRACHLORIDE REGIMEN. (Eng.) Boss, J. H.; Zajicek, G.; Rosenmann, E. (Hadassah Univ. Hosp., Mount Scopus, Israel). *J. Pathol.* 123(2):85-92; 1977.

The pattern of urinary excretion of alpha-fetoprotein (AFP) in the course of the development of liver cirrhosis induced by carbon tetrachloride was studied in rats, and compared with that in animals maintained on a hepatocarcinogenic regimen (3'methyl-4-dimethylaminoazobenzene, 0.06% in the diet). AFP was detected in the serum and urine of 2- to 9-month-old rats subjected to protracted CCl_4 (0.1 ml/100 g, s.c., twice weekly) poisoning. During the first 3 months of the experiment, urinary excretion of AFP was found in 30-40% of the animals, increasing to 70% thereafter. The liver lesions progressed from acute parenchymal necrosis to cirrhosis, but hepatocellular carcinomas did not develop. Uptake of tritiated thymidine by the hepatocytes increased significantly but was constant throughout the experimental period. In the rats fed the carcinogenic diet, the incidence of AFP excretion decreased from 35% at 4-7 weeks to 20% at 10-16 weeks after beginning the regimen; during the former period, the difference in the incidence of positive urine specimens was significantly different from that in the rats fed the CCl_4-containing diet ($p<0.05$). It may be argued that the failure to induce hepatomas was related to the short timespan of the experiment (too short for tumorigenesis to be manifested). Unfortunately, however, none of the rats survived beyond the 7th month of CCl_4 treatment.

1898 HEPATOTOXIC RESPONSE TO SINGLE OR REPEATED INJECTIONS OF N-NITROSOPYRROLIDINE IN THE RAT.

(Eng.) Hendy, R.; Grasso, P. (British Industrial Biological Res. Assoc., Woodmansterne Rd., Carshalton, Surrey SM5 4DS, England). *Chem. Biol. Interact.* 18(3):309-326; 1977.

The acute hepatotoxic effects of *N*-nitrosopyrrolidine (NPY) were studied in Wistar rats. Twenty-four hours after a single NPY dose of 100 mg/kg, centrilobular fatty change and inflammatory cell infiltrate occurred. There was no cell necrosis. Cytochemically, the centrilobular and mid-zonal areas showed autophagy, reduction in lysosomes, and a depression of glucose-6-phosphatase. Less severe changes occurred after a single dose of 30 mg/kg, and there were no detectable alterations after 10 mg/kg. Repeated daily injection of 100 or 30 mg/kg led to megalocytosis of hepatocytes after six doses. Because rats were unable to survive more than 7 NPY doses of 100 mg/kg levels of 30, 10, or 3 mg/kg were administered daily for up to 12 weeks. By 8-12 weeks, most hepatocytes in the centrilobular area were enlarged, and glucose-6-phosphatase activity was low. The lysosomal activity was variable; in some cells it resembled controls, and in others there were few lysosomes scattered haphazardly throughout the hepatocyte. Cells with this low lysosomal activity at 12 weeks generally grouped in island-like areas and ultrastructurally were rich in smooth endoplasmic reticulum. Only marginal changes were observed in rats that received 3 mg/kg throughout this period. PAS-positive, iron-containing pigment filled the Kupffer cells in all rats treated for more than 6 days with 30 mg/kg. The hepatomegalocytes resemble those produced by pyrrolizidine alkaloids, which may imply an antimitotic effect similar to that exerted by NPY on primary rat kidney cells in culture.

1899 THE SYNTHESIS OF TOTAL AND SPECIFIC GLYCOSAMINOGLYCANS DURING DEVELOPMENT OF EXPERIMENTAL LIVER CIRRHOSIS.

(Eng.) Gressner, A. M.; Pazen, H.; Greiling, H. (Medical Faculty RWTH, Goethestrasse 27-29, D-51 Aachen, W. Germany). *Experientia* 33(10):1290-1292; 1977.

The synthesis of total and of specific types of glycosaminoglycans (GAG) was studied in explants from chronically injured rat liver at various stages of fibrogenesis. During hepatic fibrogenesis induced by long-term administration of thioacetamide (0.03% in drinking water for 1-7 months), the synthesis of chondroitin 4,6-sulfate was enhanced by 70% and 100% at 1 and 2.5 months, resp., and hyaluronic acid synthesis was increased 5- to 20-fold at various intervals throughout the 7-month period. The formation of heparan sulfate (comprising at least 70% of total liver GAG synthesis) and of a keratan-sulfate-like fraction was stimulated 1.7-fold. The formation of dermatan-sulfate in the liver was not detected. This may be due either to inappropriate conditions used, or it might reflect an exceptional metabolism of this type of GAG. The studies show that the rate of synthesis of individual GAG in normal and diseased liver is very unequal.

1900 PRIMARY BILIARY CIRRHOSIS. STUDY OF THE ACTION OF MITOCHONDRIAL ANTIBODY PLUS COMPLEMENT ON MITOCHONDRIAL MEMBRANE FUNCTIONS.

(Eng.) Fernandez-Cruz, E.; Bootello, A.; Blanco, M. F.; Gosalvez, M.; Segovia de Arana, J. M. (Servicio de Immunologia, Clinica Puerta de Hierro, San Martin de Porres, Madrid-35, Spain). *Allergol. Immunopathol. (Madr.)* 4(2):145-152; 1976.

To determine the possible pathogenic role of humoral antibodies reacting with subcellular organ antigens in primary biliary cirrhosis, whole rat liver mitochondria were exposed to mitochondrial antibodies from patients with primary biliary cirrhosis and to antibodies induced in rabbits to rat liver mitochondrial antigens. Mitochondrial respiratory control and oxidative phosphorylation were not significantly altered by incubation of the whole mitochondria with rabbit or human normal or IgG; the results did not change after the addition of complement. Incubation of submitochondrial particle suspensions with normal or immune human or rabbit IgG, using succinate and NADH as substrate, also had no effect on mitochondrial respiration. Again, the addition of complement did not alter the results. ATPase activity and the swelling and contraction of intact mitochondria were not affected by the incubation procedures. The results suggest that mitochondrial antibodies do not play an important role in the pathogenesis of primary biliary cirrhosis.

1901 INHIBITION OF Na^+, K^+-ADENOSINETRIPHOSPHATASE BY ENDOTOXIN: A POSSIBLE MECHANISM FOR ENDOTOXIN-INDUCED CHOLESTASIS. (Eng.)

Utili, R.; Abernathy, C. O.; Zimmerman, H. J. (Clinica delle Malattie Infettive, I Facolta di Medicina, Universita di Napoli, Via Cotugna 1, Napoli 80135, Italy). *J. Infect. Dis.* 136(4):583-587; 1977.

To examine the possibility that the cholestatic effect of *Escherichia coli* or *Salmonella enteritidis* endotoxin might be mediated by the inhibition of the Na^+,K^+-ATPase of the canalicular membrane, the effects of lipopolysaccharides (LPS) of *E. coli* and *S. enteritidis* on the Na^+,K^+-adenosine triphosphatase (ATPase) in canalicular-enriched plasma membranes were examined in the rat liver. At 20 μg/ml, both endotoxins inhibited this enzyme by approximately 40%. Maximal inhibition (70-80%) occurred at concentrations of 120 μg/ml or greater. The LPS of neither organism had any effect on the activity of Mg^{++}-ATPase or 5'-nucleotidase in the same preparations. Inhibition by the *E. coli* LPS appeared to be noncompetitive in nature, and the calculated K_i was 45 μg/ml. Since the Na^+,K^+-ATPase may be responsible for the elaboration of the bile salt-independent fraction, inhibition of this enzyme could be the underlying mechanism for endotoxin-induced cholestasis.

1902 STUDIES ON DRUG-INDUCED CHOLESTASIS: EFFECT OF ETHINYL ESTRADIOL ON HEPATIC BILE ACID RECEPTORS AND (Na^+-K^+)-ATPase. (Eng.)

Simon, F. R.; Sutherland, E.; Accatino, L.; Vial, J.; Mills, D. *In: Bile Acid Metabolism in Health and Disease. Proceedings of the IV Bile Acid Meeting held at the Hilton Hotel, Basel, Switzerland, October 11-12, 1976.* University Park Press (Baltimore, MD): 133-143; 1977.

Since ethinyl estradiol administration reduces bile acid transport and bile acid-independent bile flow, the effect of its administration on hepatic ultrastructure, bile acid binding parameters, and the activity of (Na^+-K^+)-ATPase activity was examined. Following administration of ethinyl estradiol (5 mg/kg/day, 5 days), both scanning as well as electron microscopy demonstrated a normal bile canalicular membrane appearance. In addition, the number of sites and dissociation constant for specific binding of $[^{14}C]$cholic acid to liver surface membranes isolated from ethinyl estradiol-treated rats were unaltered compared to controls. In contrast, (Na^+-K^+)-ATPase was reduced to 46% of the control value, consistent with reduced bile flow (61% of control). Simultaneous administration of phenobarbital (80 mg/kg/day) with ethinyl estradiol prevented reductions in both bile flow and (Na^+-K^+)-ATPase. These studies demonstrate that ethinyl estradiol reduces hepatic (Na^+-K^+)-ATPase activity consistent with its role in regulation of bile salt-independent bile flow. Failure to demonstrate alterations in the initial step in bile acid transport suggest that abnormalities in translocation such as altered ion gradients or changes in the surface membrane lipid environment may be responsible for decreased bile acid transport.

1903 HEPATITIS B e ANTIGEN AND INFECTIVITY OF HEPATITIS B VIRUS. (Eng.)

Shikata, T.; Karasawa, T.; Abe, K.; Uzawa, T.; Suzuki, H.; Oda, T.; *et al.* (Nihon Univ. Sch. Medicine, 30 Kamimachi Oyaguchi Itabashi-ku, Tokyo, 173 Japan). *J. Infect. Dis.* 136(4):571-576; 1977.

To confirm the difference in the infectivity of hepatitis B surface antigen (HBsAg)-positive serum according to differences in the e antigen system, four chimpanzees were inoculated i.v. with serum positive for hepatitis B e antigen (HBeAg), and three chimpanzees were inoculated with serum positive for antibody to HBeAg (anti-HBe). Since the infectivity titrations are not yet completed, the end infectivity titer of each serum is not known. All four chimpanzees that received 10^{-1}, 10^{-4}, or 10^{-8} dilutions of HBeAg-positive serum developed hepatitis B virus infection, whereas the one animal injected with undiluted anti-HBe-positive serum became infected, and other chimpanzees injected with diluted anti-HBe-positive sera did not. As judged from the length of the incubation period before appearance of HBsAg in blood, there was a remarkable difference in infectivity between the HBeAg-positive serum and the anti-HBe-positive serum; the former serum was 10^8 times more infectious than the latter. This study confirms the infectivity of HBsAg-positive serum containing anti-HBe and the difference in the infectivity depending upon whether HBeAg or anti-HBe is present.

1904 EARLY EFFECTS OF HYPERVITAMINOSIS A ON GLUCONEOGENIC ACTIVITY AND AMINO ACID METABOLIZING ENZYMES OF RAT LIVER. (Eng.)

Dileepan, K. N.; Singh, V. N.; Ramachandran, C. K. (Vallabhbhai Patel Chest Inst., Univ. Delhi, Delhi-110007, India). *J. Nutr.* 107(10):1809-1815; 1977.

The effects of feeding retinyl palmitate to young rats (80-100 g) on the incorporation of ^{14}C-labeled precursors into glucose and glycogen by liver slices, the levels of amino acids in blood and tissues, and the activities of some important amino acid catabolizing enzymes in the liver were investigated. The rats received 30,000 IU of retinyl palmitate daily for 2 days. A stimulation of hepatic gluconeogenesis in hypervitaminosis A was indicated by the increased incorporation of ^{14}C-labeled alanine and bicarbonate into glucose and glycogen by liver slices. Excessive intake of retinol caused a marked increase in the activities of hepatic alanine aminotransferase and ornithine aminotransferase and a decrease in that of tryptophan pyrrolase, without affecting those of tyrosine aminotransferase and serine dehydratase. The ratio of NADH:NAD in the livers of rats fed excess retinol was significantly increased. The enhancement of gluconeogenesis seen in hypervitaminosis A is caused by a stimulation of gluconeogenic activity of the liver.

1905 EFFECT OF INTERMITTENT PHOTOTHERAPY ON BILIRUBIN DYNAMICS IN GUNN RATS.

(Eng.) Vogl, T. P.; Cheskin, H.; Blumenfeld, T. A.; Speck, W. T.; Koenigsberger, M. R. (Box 4, Babies Hosp., 630 W. 168th St., New York, NY 10032). *Pediatr. Res.* 11(10, Part 1):1063-1068; 1977.

To determine whether continuous phototherapy is necessary to control neonatal jaundice, groups of jaundiced (Gunn) rats were exposed to four blue-light regimens: continuous light, 30 min light/30 min dark, 6 min light/6 min dark, and 6 min light/18 min dark. An exponential decrease in serum bilirubin concentration (SBC) was found with all regimens. A logarithmic dose response curve was obtained with a 50% light dose exhibiting 75% efficacy, and a 25% light dose exhibiting 59% efficacy compared to continuous phototherapy. The time constants of the decrease in serum bilirubin concentration also varied logarithmically with doses, with continuous therapy having a time constant of 1.4 days, and 6 min light/18 min dark therapy having a time constant of 3 days. It is concluded that, for adult Gunn rats, and probably for neonates, an optimum combination of light intensity and on/off cycle time exists that represents a therapy regimen that produces optimal therapeutic benefit while minimizing total light dosage.

1906 EFFECT OF RENAL ISCHAEMIA IN RATS WITH OBSTRUCTIVE JAUNDICE.

(Eng.) Craddock, G. N.; Lee, E. (Addenbrooke's Hosp., Cambridge, England). *Ann. R. Coll. Surg. Engl.* 59(5):409-414; 1977.

The quantitative relationship between obstructive jaundice and renal susceptibility to ischemia was investigated in female white Wistar rats. The bile ducts of 51 rats were ligated, while those of another 51 were unligated. All animals experienced occlusion of the left kidney one week later for periods of 0-230 min. Three weeks later, the right kidney was removed. Nonjaundiced animals had a mean right kidney weight of 0.394 ± 0.024% of body weight when no left renal ischemia was imposed; the right kidney was 0.519 ± 0.034% of body weight after 230 min of left renal ischemia. Jaundiced rats displayed a mean right kidney weight of 0.470 ± 0.050% of body weight without ischemia and 0.589 ± 0.054% with maximal compensatory hypertrophy. Both jaundiced and nonjaundiced animals had a LD_{50} of renal ischemia of 120 min after delayed opposite nephrectomy. These results show no significant difference between the two groups of animals, except the marked increase in renal weight in the presence of jaundice. No significant difference in susceptibility to renal ischemia could be demonstrated in rats with or without obstructive jaundice.

1907 THE ACCELERATION OF HEPATIC REGENERATION BY PRIOR LAPAROTOMY.

(Eng.) Sakamoto, Y.; Jehn, D.; Nicolson, M. O.; Ohashi, E.; Hays, D. M. (Univ. Southern California Sch. Medicine, 4650 Sunset Blvd., Los Angeles, CA 90027). *J. Surg. Res.* 23(5):306-310; 1977.

The effect of laparotomy, carried out as a "stress" procedure, prior to partial hepatectomy on liver regeneration was studied in male Fischer rats. Laparotomy consisted of a 5.5-cm mid-line lower abdominal incision with mobilization of the viscera for 5 min. Laparotomy, carried out 6 hr prior to 68% hepatectomy, accelerated the initial rise and first peak of DNA synthesis by approximately 3 hr and the second peak by approximately 6 hr. The effect was most striking in the 16-hr post-resection liver in which [^{3}H]thymidine incorporation in animals stressed by prior laparotomy was >25 times that found in unstressed animals. These studies suggest that an initial phase of the response to hepatic resection may be initiated by nonspecific trauma that is of sufficient magnitude and administered at an appropriate interval prior to hepatectomy.

1908 GLIAL CHANGES IN PIGS WITH PORTO-CAVAL ANASTOMOSIS AND TEMPORARY OR TOTAL HEPATIC ARTERY CLAMPING.

(Eng.) Diemer, N. H.; Tonnesen, K. (Inst. Neuropathology, Univ. Copenhagen, 11 Frederik V's Vej, DK-2100 Copenhagen O, Denmark). *Acta Pathol. Microbiol. Scand.* [*A*] 85(5):721-730; 1977.

To investigate neurological changes in hepatic encephalopathy and in portacaval anastomosis (PCA), the number and size of astrocyte, oligodendrocyte, and neuron nuclei were determined in the cortex and corpus striatum (putamen) of pigs with PCA and total or temporary clamping of the hepatic artery. Animals with PCA and total clamping became comatose and died on average 18.5 hr postoperatively. Their brains showed slight edema but no changes in the glial and neuron nuclear numbers. Animals with PCA and temporary clamping of the hepatic artery (30-60 min) all survived without developing encephalopathy. However, the brains showed vacuolization of the deeper cortical layers, diffuse occurrence of Alzheimer type II astrocytes, and the counts revealed an increased number of astrocytic nuclei. The total number of glial cells decreased due to loss of oligodendrocytes, but the number of neurons was unchanged. The findings indicate that the neuropathological changes after PCA and temporary hepatic artery clamping are concerned primarily with changes of the glial cells.

1909 THE MECHANISM OF POSTSHUNT LIVER FAILURE.

(Eng.) Reichle, F. A.; Rao, N. S.; Reichle, R. M.; Chang, K. H. Y. (Temple Univ. Health Sciences Center, Philadelphia, PA 19140). *Surgery* 82(5):738-749; 1977.

To investigate the mechanism of postshunt liver failure, postoperative hepatic mass, body weight, ammonia clearance, hepatic urea cycle enzyme activity, and hepatic protein metabolism were determined in 59 dogs that underwent sham operation, end-to-side portacaval shunt, mesocaval shunt with subsequent end-to-side portacaval shunt, distal splenorenal shunt, caval left portal shunt, or portal venous segregation with jugular vein interposition. Compared to total shunt, selective diversion of portal blood from the liver produced less post-shunt liver atrophy, less body weight loss, improved maintenance of urea cycle enzyme activity, improved ammonia tolerance, and less decrease in hepatic DNA, RNA, and protein content. Segregation of left from right hepatic lobes, in relation to portal or systemic venous hepatic perfusion or in relation to gastroduodenopancreaticosplenic or intestinal portal venous drainage, caused little change in enzyme or protein metabolism in respective hepatic lobes.

1910 CHANGES IN THE ACTUAL OXYGEN LEVEL OF THE LIVER DURING BARBITURATE-HALOTHANE ANESTHESIA. (Ger.) Szelenczy, M.; Kiss, T. (Second Surgical Clinic, Pecs Medical Univ., Pecs, Hungary). *Z. Exp. Chir.* 10(3):156-160; 1977.

1911 EVALUATION OF CERTAIN BIOCHEMICAL PARAMETERS IN THE COURSE OF LIVER PERFUSION AT VARYING TEMPERATURES. (Ita.) Motta, G.; Ratto, G. B.; Venturini, M.; De Luca, L.; Bergomi, B.; Nahum, M. (Istituto de Patologia Chirurgica dell' Universita di Genova, Genoa, Italy). *Boll. Soc. Ital. Biol. Sper.* 52(14):1042-1048; 1976.

SECRETION AND METABOLISM

Intestine

1964 DEVELOPMENT OF SUBSTRATE CYCLE ENZYMES IN THE HAMSTER SMALL INTESTINE. (Eng.) Schiller, C.; Walden, R. (Natl. Inst. Environmental Health Sciences, P.O. Box 12233, Research Triangle Park, NC 27709). *Dev. Biol.* 60(1):130-138; 1977.

The patterns of development of four substrate cycle enzymes, assayed from intestinal tissue subcellular fractions of Syrian fetal, neonatal, and adult LVG/LAK hamsters were studied. NAD-linked L-glycerol-3-phosphate dehydrogenase (NAD-G_3PDH), flavoprotein-linked L-glycerol-3-phosphate dehydrogenase (Fp-G_3PDH) L-malate dehydrogenase (MDH), and GOT were measured in the mitochondria and/or the cytosol by spectrophotometry. Cytosolic NAD-G_3PDH activity increased from low fetal levels (0.0140 ± 0.0021 mmol/min/mg) to a maximum level 7 days after birth (0.1000 ± 0.0428 mmol/min/mg), and then decreased to adult levels (0.0695 ± 0.0053 mmol/min/mg). Mitochondrial Fp-G_3PDH activity increased at 7 days after birth (0.0219 ± 0.0035 mmol/min/mg) to levels slightly lower than those of adults (0.0228 ± 0.0054 mmol/min/mg). MDH in both the cytosol and mitochondrial fractions increased from fetal levels (1.35 ± 0.15 and 3.80 ± 0.45 mmol/min/mg, resp.) comparable to adult levels to a postnatal peak (2.81 ± 0.20 and 6.85 ± 0.74 mmol/min/mg, resp.). GOT activity in both subcellular fractions was high prenatally (0.131 ± 0.015 and 0.558 ± 0.035 mmol/min/mg, resp.), with a postnatal peak at 7 days (0.197 ± 0.028 and 0.459 ± 0.107 mmol/min/mg, resp.), at which time it declined to adult levels (0.121 ± 0.009 and 0.225 ± 0.034 mmol/min/mg, resp.). These results indicate that the 7-day postnatal period represents a peak in mitochondrial and cytosolic enzyme development.

1965 PATHOGENESIS OF MUCOSAL INJURY IN THE BLIND LOOP SYNDROME: BRUSH BORDER ENZYME ACTIVITY AND GLYCOPROTEIN DEGRADATION. (Eng.) Jonas, A.; Flanagan, P. R.; Forstner, G. G. (Hosp. Sick Children, Toronto, Canada). *J. Clin. Invest.* 60(6):1321-1330; 1977.

The effect of surface damage in intestinal bacterial overgrowth on brush border hydrolases and brush border glycoproteins was studied in nonoperated control rats, control rats with surgically introduced jejunal self-emptying blind loops, and rats with surgically introduced jejunal self-filling blind loops. Data were analyzed from blind loop segments, segments above and below the blind loops, and three corresponding segments in the nonoperated controls. Rats with self-filling blind loops had significantly greater fat excretion (6.9 ± 1.3% of intake) than nonoperated controls (2.1 ± 0.3%, $p<0.001$) or controls with self-emptying loops (2.7 ± 0.1%, $p<0.01$) and exhibited significantly lower conjugated:free bile salt ratios in all three segments. Maltase, sucrase, and lactase activities were significantly reduced in homogenates and isolated brush borders from the self-filling blind loop, but alkaline phosphatase was not affected. The relative degradation rate of homogenate and brush border glycoproteins was assessed by a double-isotope technique involving the injection of D-[6-^{3}H]glucosamine at 3 hr and D-[U-^{14}C]glucosamine at 19 hr before sacrifice and was recorded as a ^{3}H:^{14}C ratio. The relative degradation rate in both homogenate and brush border fractions was significantly greater in most segments from rats with self-filling blind loops. In the upper and blind loop segments from rats with self-filling blind loops, the ^{3}H:^{14}C ratios were higher in the brush border membrane than in the corresponding homogenates, indicating that the increased rates of degradation primarily involve membrane glycoproteins. The incorporation of D-[6-^{3}H]glucosamine by brush border glycoproteins was not reduced in rats with self-filling blind loops, suggesting that glycoprotein synthesis was not affected. Polyacrylamide gel electrophoresis of brush border glycoproteins from the contaminated segments indicated that the large molecular weight glycoproteins, which include many of the surface hydrolases, were degraded most rapidly. Brush border maltase, isolated by immunoprecipitation, had ^{3}H:^{14}C ratios characteristic of the most rapidly degraded glycoproteins. The results indicate that bacteria enhance the destruction of intestinal surface glycoproteins including disaccharidases. Since alkaline phosphatase is not affected, the destruction is selective and presumably involves only the most exposed membrane components.

1966 REGIONAL LOCALIZATION OF ACTIVITY OF Clostridium perfringens TYPE A ENTEROTOXIN IN THE RABBIT ILEUM, JEJUNUM, AND DUODENUM. (Eng.) McDonel, J. L.; Duncan, C. L. (Dept. Microbiology and Cell Biology, Pennsylvania State Univ., University Park, PA 16802). *J. Infect. Dis.* 136(5): 661-666; 1977.

In an effort to characterize and compare the responses of the three parts of the small intestine to *Clostridium perfringens* enterotoxin for future studies on the mode of action of the toxin, rabbit ileal, jejunal, and duodenal loops were exposed to purified enterotoxin from *C. perfringens* type A and then perfused for comparative analysis of the effects of the enterotoxin on each region of the intestine. Ileal loops responded with enhanced net secretion of fluid and sodium, inhibition of chloride and glucose uptake, and substantial sloughing of epithelial cells. The jejunum responded with fluid secretion, enhancement of sodium secretion (only during the first 20 min), inhibition of chloride and glucose uptake, and substantial sloughing of epithelial cells. In the duodenum, transport of fluid, sodium, and chloride was significantly altered only during the first 20 min of perfusion, and significant inhibition of glucose uptake varied from one period to another. Epithelial damage was much less than that seen in the jejunum or ileum. Levels of fluid protein in all three sections corresponded closely to extent of tissue damage. The severity of response to fixed doses of enterotoxin generally varied as follows: ileum>jejunum>duodenum.

1967 A RABBIT MODEL OF DIARRHEA DUE TO INVASIVE Escherichia coli. (Eng.) Cantey, J. R.; O'Hanley, P. D.; Blake, R. K. (Veterans Admin. Hosp., 109 Bee St., Charleston, SC 29403). *J. Infect. Dis.* 136(5):640-648; 1977.

Rabbits received a nonpiliated strain of invasive *Escherichia coli* of human origin (HInvEC) in doses ranging from 1.5 x 10^8 to 2.5 x 10^{10} bacteria, in an effort to develop a convenient model of *E. coli* (HInvEC) diarrhea. This strain colonized the ileum, cecum, and colon in large numbers for 1-3 days and produced diarrhea in 91 (58%) of the 156 rabbits. A dose of 2.5 x 10^{10} bacteria reliably and repeatedly elicited diarrheal disease in 80% of the animals. The acute pathohistology as determined by light microscopy, transmission electron microscopy, and immune fluorescent microscopy was manifest in the distal ileum, cecum, and colon. Prominent findings included mucosal ulcers, bacterial invasion of the lamina propria, and a polymorphonuclear infiltrate in the lamina propria. Diarrhea due to strain HInvEC was followed by a rise in the titer of serum antibody to O antigen of *E. coli*. Because the rabbit is so well characterized immunologically, this model should be especially valuable in determining the nature of the local immune response and the effects of that response on the infection of the gut by bacteria that cause diarrhea.

GENERAL

1983 HISTAMINE H_1- AND H_2-RECEPTOR VASODILATION OF CANINE INTESTINAL CIRCULATION. (Eng.) Pawlik, W.; Tague, L. L.; Tepperman, B. L.; Miller, T. A.; Jacobson, E. D. (Univ. Texas Medical Sch., Houston, TX 77025). *Am. J. Physiol.* 233(3): E219-E224; 1977.

The local vasodilator response to histamine in the superior mesenteric artery of anesthetized dogs was studied to determine whether the mesenteric vasodilator response to histamine is mediated by H_1 receptors alone or whether H_2 receptors are also involved in the response. The vasodilator response to histamine was inhibited by either the H_1-receptor antagonist, tripelennamine, or the H_2-receptor antagonist, metiamide. Both the H_1 agonist, 2-methylhistamine, and the H_2 agonist, 4-methylhistamine, induced dilator responses in the mesenteric circulation. Two temporal patterns of vasodilation were distinguished: a transient spike and subsequent fade of blood flow (seen with either the H_1 agonist or with histamine after H_2-receptor blockade) and a sustained and stable increase in flow (seen with either the H_2 agonist or with histamine after H_1 blockade). Metiamide appeared to be a potent inhibitor of the mesenteric vasodilator response to histamine at least equal to tripelennamine. The results suggest that the mesenteric vasodilator response to histamine is mediated by both H_1 and H_2 receptors.

1984 THE PROTECTIVE EFFECT OF VANCOMYCIN ON CLINDAMYCIN-INDUCED COLITIS IN HAMSTERS.

(Eng.) Browne, R. A.; Fekety, R., Jr.; Silva, J., Jr.; Boyd, D. I.; Work, C. O.; Abrams, G. D. (Dept. Internal Medicine, Univ. Michigan, Ann Arbor, MI 48109). *Johns Hopkins Med. J.* 141(4):183-192; 1977.

To determine whether changes in intestinal flora have a pathogenetic role in clindamycin-associated colitis and are influenced by p.o. nonabsorbable antibiotics, the effect of vancomycin on clindamycin-induced colitis was studied in hamsters. Vancomycin significantly prolonged survival and sometimes prevented death in clindamycin-treated (100 mg/kg, s.c.) hamsters, even if treatment was delayed until 48 hr after clindamycin challenge. Oral vancomycin was more protective than s.c. vancomycin in comparable doses (200 μg/ml in drinking water; 3 mg, s.c.). Vancomycin itself was frequently lethal to hamsters, but the mechanism of toxicity was unclear. Histologic studies demonstrated that vancomycin prevented clindamycin-induced intestinal lesions, although similar lesions frequently evolved after treatment with vancomycin was discontinued. Hamsters given a single injection of clindamycin and subsequently treated with continuous p.o. vancomycin for as long as 12 weeks often died after vancomycin was stopped, with lesions indistinguishable from those seen in clindamycin-induced enterocolitis. Oral vancomycin was not significantly absorbed from the intestinal tract of hamsters. Bacteremia was frequent in clindamycin-treated hamsters in the 72 hr post-challenge, and the incidence of bacteremia was unchanged by p.o. vancomycin. In humans, p.o. vancomycin is nontoxic and may be useful in prevention or treatment of clindamycin-associated colitis.

1985 ELECTROKINETIC PROPERTIES OF LYMPHOCYTES SEPARATED FROM MOUSE PEYER'S PATCHES.

(Eng.) Dumont, F.; Robert, F. (Unit Experimental Cancerology and Radiology, INSERM U-95, Plateau de Brabois, 54500 Vandoeuvre-les-Nancy, France). *Immunology* 33(3):295-303; 1977.

The electrophoretic mobility (EPM) of lymphocyte populations isolated from murine Peyer's patches (PP) was characterized to determine whether bone marrow-derived (B) lymphocytes can be distinguished from thymus-derived (T) cells by their lower EPM, as they can in peripheral lymphoid tissues. Electrokinetic properties were investigated using both analytical and preparative cell electrophoresis, and conventional serologic and mitogenic markers for B and T cells were determined in parallel. In CBA mice, PP cells, which included 44% surface-immunoglobulin positive (sIg+) cells and 23% Thy-1-2-positive cells, were found to be composed of two distinct electrophoretic populations. The major one (66% of PP cells) with a mean EPM of 0.70 μm/sec/V/cm was designated as the low-mobility (LM) population, the other one with a mean EPM of 1.16 μm/sec/V/cm was designated as the high-mobility (HM) population. LM cells were encountered in lower frequency (9%) in B lymphocyte-depleted, PP (5% sIg+) from cyclophosphamide-treated CBA mice but were preponderant (92%) in the B lymphocyte-enriched (80% sIg+) nylon-adherent PP cells. In contrast, HM cells made up the majority of cyclophosphamide-resistant PP cells and of nylon-nonadherent PP cells, which were shown to be enriched in T lymphocytes (70 and 63% Thy-1-2$^+$ cells, resp.). On the other hand, following fractionation of CBA PP cells by free-flow preparative electrophoresis, sIg+ cells were distributed in the LM region and Thy-1-2$^+$ cells in the HM region. Moreover, in T lymphocyte-deficient athymic nude mice, PP cells, which were 70% sIg+, were found to be exclusively of LM type (mean EPM=0.77 μm/sec/V/cm). Thus, although both electrophoretic populations included sIg and Thy-1-2-negative elements, it appears that in murine PP as in spleen, most B lymphocytes are endowed with a low EPM and T lymphocytes with a higher EPM.

1986 EN BLOC TRANSPLANTATION OF THE LIVER, PANCREAS, DUODENUM, SPLEEN, AND KIDNEY IN THE RAT.

(Eng.) Maki, T.; Sakai, A.; Pettirossi, O.; Kountz, S. L. (Downstate Medical Center, Brooklyn, NY 11203). *Transplantation* 24(4):256-262; 1977.

The fate of the liver, pancreas, duodenum, spleen, and kidneys from (Lewis x Brown Norway)F_1 rats was studied after they were transplanted simultaneously as an *en bloc* graft to Lewis recipients. No immunosuppression was given postoperatively. Serial laparotomies were performed for macroscopic examination and biopsies of the grafts. Macroscopically, the first evidence of rejection was splenic enlargement followed by fatty metamorphotic change of the liver, dilation and loss of peristalsis of the duodenum, and injection and edema of the pancreas. The kidneys maintained normal color and consistency until late in the rejection process. Histological examination suggested that the liver and the spleen may be more vulnerable to immune attack, since in these organs cellular infiltration started earlier and was more extensive in comparison to other organs. While the pancreas exhibited a typical, although somewhat delayed rejection pattern, the kidneys seemed to maintain a well preserved structure. The duodenum showed no significant cellular infiltration throughout the postoperative period of examination, despite severe mucosal destruction. These findings indicate that the five organs are subject to different modes of rejection when transplanted simultaneously as an *en bloc* graft.

DIAGNOSTIC PROCEDURES

1994 DIAGNOSTIC ACCURACY OF FIBERENDOSCOPY IN THE DETECTION OF UPPER INTESTINAL MALIGNANCY. A FOLLOW-UP ANALYSIS. (Eng.) Dekker, W.; Tytgat, G. N. (St. Elisabeth's of Groote Gasthuis, Boerhaavelaan 22, Haarlem, Netherlands). *Gastroenterology* 73(4, Part 1):710-714; 1977.

The accuracy of fiberendoscopy with directed biopsy in the detection of upper intestinal malignancies has been evaluated by studying the operative or postmortem findings or the clinical follow-up data after at least 1 yr and, for relevant lesions, after 2 or 3 yr, in 990 patients. There were no false-positive diagnoses of malignancy in the 167 patients diagnosed fiberendoscopically to harbor an upper intestinal malignancy, and only 2 false-negative diagnoses in the 829 patients with either a benign lesion or an endoscopically normal mucosa. Seven of the 135 adenocarcinomas of the stomach turned out to be early gastric cancers. The two missed malignancies were interpreted initially as benign gastric ulcers. The over-all endoscopic-bioptic accuracy rate calculated for all patients amounts to 99.8%. Such a high accuracy rate can only be reached provided high numbers of biopsies are taken, and particularly at least 10 of gastric ulcers and of suspicious lesions. Endoscopy alone is not sufficiently reliable in determining the nature of the lesion; an incorrect endoscopic interpretation was made in 7.3% of the ulcerous lesions, and in 8.2% of them no firm conclusion could be reached.

1995 APPRAISAL OF THE ^{14}C-GLYCOCHOLATE ACID TEST WITH SPECIAL REFERENCE TO THE MEASUREMENT OF FAECAL ^{14}C EXCRETION. (Eng.) Scarpello, J. H. B.; Sladen, G. E. (Royal Hosp., West St., Sheffield, England). *Gut* 18(9):742-748; 1977.

The ^{14}C-glycocholate test, including the measurement of marker-corrected fecal ^{14}C, was assessed in 18 normal controls, 21 patients with diarrhea not attributable to altered bile acid metabolism, 12 patients with diverticula of the small intestine, 34 patients with previous resection of ileum and often proximal colon, and 10 established ileostomists. Patients with diverticular disease had increased breath $^{14}CO_2$ excretion, but normal fecal excretion of ^{14}C, and this test was more frequently abnormal than the Schilling test. Ileostomists excreted increased amounts of fecal ^{14}C, even when the ileum was intact and apparently normal. The pattern after resection was complex. Breath ^{14}C output was normal if the ileal resection was less than 25 cm in length, although some of these patients had increased fecal ^{14}C excretion if, in addition, at least 15 cm of proximal colon had been resected or bypassed. Longer ileal resections were associated with increased breath and/or fecal ^{14}C excretion, depending in part on the length of colon resected or bypassed and the 24-hr fecal volume. Fewer than half these patients had both increased breath and fecal excretion of isotope, and fecal ^{14}C alone was occasionally normal with an ileal resection of 50 cm or more. The ^{14}C-glycocholate test was more frequently abnormal than the Schilling test in this group. The use of fecal marker correction had only a minor impact on the results. These data suggest that, in patients with ileal resection, fecal ^{14}C, like fecal weight, is determined by the extent of colonic resection as well as by the amount of ileum resected.

1996 URINARY OXALATE ON A HIGH-OXALATE DIET AS A CLINICAL TEST OF MALABSORPTION. (Eng.) Andersson, H.; Gillberg, R. (Sahlgren's Hosp., S-413 45 Gothenburg, Sweden). *Lancet* 2(8040):677-679; 1977.

To investigate whether the determination of urinary oxalate can replace the determination of fecal fat as a clinical test of malabsorption, 100 g of spinach a day was added to the hospital diet of 54 patients with suspected malabsorption. Hyperoxaluria was found in 38 patients; all of them had steatorrhea No patient with steatorrhea had a urinary oxalate excretion of <40 mg/day. Ten other patients had hyperoxaluria, but the fecal fat determinations were regarded as unreliable in almost all and malabsorption could not be confirmed. In clinical practice, the determination of urinary oxalate after a p.o. load of oxalate could replace fecal fat determination in most patients with suspected malabsorption.

1997 ~~PURIFIED ANTIGEN~~ RADIOIMMUNOASSAY IN SEROLOGICAL DIAGNOSIS OF SCHISTOSOMIASIS MANSONI. (Eng.) Pelley, R. P.; Warren, K. S.; Jordan, P. (Case Western Reserve Univ., Cleveland, OH 44106). *Lancet* 2(8042):781-785; 1977.

A radioimmunoassay was developed for detecting human schistosomiasis with a highly purified *Schistosoma mansoni* egg antigen labeled with ^{125}I. With this assay, 276 sera from two patient populations from St. Lucia and Kenya were analyzed, and the results were compared with those previously obtained by the standard assays on the same St. Lucian sera. The egg antigen, major serologic antigen (MSA_1), has striking immunochemical and species specificity and appears to be the principal antigen responsible for the granulomatous response to *S. mansoni* eggs. This ^{125}I-antigen was tested with 5 μl of patient serum as a potential serodiagnostic test for schistosomiasis. Ninety-two control sera from uninfected St. Vincentian patients were seronegative. In studies on 135 mildly infected St. Lucians, the 5-μl serum $^{125}I-MSA_1$ serodiagnostic test was more sensitive than any tests available at the Center for Disease Control, with 64% of infected children, 83% of adolescents, and 98% of adults being positive. Forty-nine heavily infected Kenyans of all age groups were uniformly (100%) seropositive. Finally, a semiquantitative version of the $^{125}I-MSA_1$ radioimmunoassay that uses 0.5 μl of patient sera demonstrated quantitatively significant differences among age-matched and intensity-matched groups of patients with *S. mansoni*, *S. haematobium*, and *S. japonicum* infections. The highly sensitive complement-fixation and indirect-immunofluorescence tests have completely failed to differentiate *S. mansoni* from *S. haematobium* infections.

1998 ARTERIOGRAPHY IN PERITONITIS AND ILEUS. (Ger.) Levendjuk, A. M. (Res. Inst. General Emergency Surgery, 19, Vjezd Balakireva 1, Kharkov, USSR). *Radiol. Diagn.* 18(2):195-203; 1977.

Arteriographic changes caused by peritonitis (induced by ligation of the vermiform appendix) and ileus (induced by obturation or strangulation of the intestine) were studied in 100 adult dogs. Angiography revealed considerable changes in the local blood circulation (reduction of the linear velocity and of the flow volume) in experimental peritonitis and ileus. Constriction of the arteries was a common feature of peritonitis and ileus. The regional hemodynamic changes were most consistently pronounced in ileus caused by strangulation; the changes increased gradually in ileus caused by obturation, after which they showed a tendency toward normalization. In peritonitis, the disturbances in blood circulation were aggravated in parallel with the course of the disease; the blood flow volume dropped to a very low level at the terminal stage of peritonitis.

1999 A NON-INVASIVE TEST OF GASTRIC FUNCTION. (Eng.) Taylor, T. V.; Bone, D.; Torrance, B. (Royal Infirmary, Edinburgh, Scotland). *Br. J. Surg.* 64(10):702-708; 1977.

The results of a new, noninvasive test of gastric secretory function using ^{99m}Tc-pertechnetate are presented. Fifteen minutes after the administration of pentagastrin (6 μg/kg, i.m.) to fasted patients, ^{99m}Tc (1 mCi, i.v.) is administered, and dynamic images produced by a gamma camera are taken at 2, 10, 15, and 30 min. In a normal subject, 5.8% of the injected dose was inside the stomach after 30 min, and a clear gastric image was obtained. Scans of a patient who had undergone total gastrectomy revealed no image formed, no appreciable fall off of background activity, and zero intragastric activity. With pernicious anemia, a poor gastric outline was present, with only 1% activity recorded after 30 min. Patients with stomach fundus carcinoma showed gastric activity of 1.8% of the total dose after 30 min. A mean activity of 7.4 ± 2.5% of the dose was recorded for patients with duodenal ulcers ($p < 0.05$). A false-negative scan was obtained from a patient with dermatitis herpetiformis and celiac disease. Although these findings are preliminary, this appears to be a convenient, noninvasive technique for assaying gastric function proportional to acid output without losses due to incomplete aspiration or gastric emptying.

2000 A REAPPRAISAL OF CLINICAL, ROENTGENOGRAPHIC AND ENDOSCOPIC FEATURES OF THE ZOLLINGER-ELLISON SYNDROME. (Eng.) Regan, P. T.; Malagelada, J. R. (Mayo Clinic, Rochester, MN). *Mayo Clin. Proc.* 53(1):19-23; 1978.

The clinical, roentgenographic, and endoscopic features of 40 patients with Zollinger-Ellison syndrome were evaluated in an attempt to update the diagnostic criteria of this entity. The patient group (26 without prior gastric surgery, 9 with vagotomy and partial gastrectomy, 2 with partial gastrectomy, and 3 with vagotomy and pyloroplasty) exhibited at least two of the following three criteria: (1) hypergastrinemia (gastrin serum levels >300 pg/ml), (2) gastric hypersecretion (basal acid output >15 mEq in previously unoperated patients, >5 mEq in patients with prior gastric surgery), or (3) histopathologic demonstration of an endocrine-type tumor at operation. Sixty percent of the patients were men, and the mean age was 50.5 yr. The mean duration of gastrointestinal symptoms (abdominal pain, diarrhea, or bleeding) prior to diagnosis was 77.9 months. In one-half of the patients with Zollinger-Ellison syndrome, the clinical, roentgenographic, and endoscopic findings were similar to those indicating duodenal ulcer or erosive duodenitis. In conclusion, along with clinical, roentgenographic, and endoscopic studies, routine diagnostic use of serum gastrin radioimmunoassay and gastric analysis is suggested for a more efficient diagnosis of this syndrome.

2001 COMPARISON OF ULTRASOUND AND COMPUTER-ASSISTED TOMOGRAPHY IN PANCREATIC DIAGNOSIS. (Eng.) Husband, J. E.; Meire, H. B.; Kreel, L. (Royal Marsden Hosp., Downs Rd., Sutton, Surrey, SM2 5PT, England). *Br. J. Radiol.* 50(600): 855-862; 1977.

In 50 patients with suspected pancreatic disease, both ultrasonography and computerized tomography (CT) were performed to confirm the diagnosis. A grey scale ultrasound machine and the prototype of the EMI whole-body scanner were used. Both investigations were carried out on the same day in each patient. The final diagnosis was obtained either by laparotomy, by post mortem, or by strong biochemical or clinical evidence. CT visualized the pancreas in 100% of the patients, whereas ultrasound was successful in 80%. The ultrasound failures were due to bowel gases anterior to the pancreas. The diagnosis in normal patients was correct in 12 of 14 patients when ultrasound examination was performed and in 11 patients using CT. Acute pancreatitis was successfully diagnosed by ultrasonography in six of eight patients. Chronic pancreatitis was correctly diagnosed in eight patients (50%) using ultrasound, while CT demonstrated the disease in 14 of 16 patients. Ultrasound diagnosed only five of nine cases of carcinoma, while CT correctly diagnosed all carcinomas. Both techniques failed to detect lesions in either of two patients with endocrine tumors. Both ultrasonography and CT correctly diagnosed pancreatic lymphoma in one patient with this tumor. If both techniques are available, ultrasound may be used as a screening procedure from which about 15% of patients may be referred for other diagnostic procedures, including CT.

2002 PREOPERATIVE DIAGNOSIS OF PANCREATIC CARCINOMA BY PERCUTANEOUS ASPIRATION BIOPSY. (Eng.) Goldman, M. L.; Naib, Z. M.; Galambos, J. T.; Rude, J. C., III; Oen, K. T.; Bradley, E. L., III; *et al.* (Grady Memorial Hosp., 80 Butler St., S.E., Atlanta, GA 30303). *Am. J. Dig. Dis.* 22 (12):1076-1082; 1977.

Percutaneous aspiration biopsy was used in the preoperative differential diagnosis of pancreatic carcinoma and pancreatitis in 13 patients with suspected pancreatic malignancies. The pancreatic cancer was localized for aspiration biopsy by the combination of ultrasonography and angiography or cholangiography. The skin directly overlying the main portion of the pancreatic mass (as determined by ultrasonography) was punctured with a Chiba needle, and under fluoroscopic guidance, the needle was directed to the region of abnormal vessels seen by angiography. In all of the 13 aspirations that were performed, recognizable pancreatic glandular and duct cells were obtained. Carcinoma of the pancreas was documented by angiography, clinical follow-up, or by histology in 11 patients. In six of these patients, adenocarcinoma was confirmed. In a seventh patient, the cytological material was suspicious of cancer. One positive finding was from a patient with a small tumor less than 3 cm in diameter localized in the head of the pancreas. The other positive findings were from patients with tumors ranging in diameter from 3 to over 6 cm. In the four patients in whom aspiration biopsy was not diagnostic, the carcinoma was large in one, moderate in one, and small in two. Following percutaneous aspiration biopsy, none of the 13 patients had clinical or laboratory evidence of pancreatitis or worsening of their clinical condition. Percutaneous aspiration biopsy appears to be a safe procedure that should be considered in the evaluation of patients with suspected pancreatic malignancy in which a mass lesion is demonstrated by ultrasonography, computerized tomography, angiography, or retrograde pancreatography.

2003 DUODENOSCOPIC GUIDED BIOPSY OF THE BILIARY AND PANCREATIC DUCT. (Eng.) Seifert, E.; Urakami, Y.; Elster, K. (1. Med. Klinik, Stadt. Krankenhaus Kemperhof, D-5400 Koblenz, W. Germany). *Endoscopy* 9(3):154-161; 1977.

A specially designed forceps was used to perform duodenoscopic guided biopsy of the biliary and pancreatic duct in 11 patients. The special forceps, which has a tip that can be bent like an ordinary intubation cannula, was inserted via the instrumentation channel of the duodenofiberscope into the papilla of Vater and was guided to the lesion by fluoroscopy. When the lesion was reached, the biopsy was taken in the usual way. The method was used to gain histological material in 10 of the 11 patients examined. In one case, the forceps could not be inserted into the papilla. The method gave good and representative results in the biliary duct and from the papilla. Biopsies taken from inside of carcinomatous papillae gave, in both cases, positive results; also, a case of adenomyomatosis of the papilla of Vater was confirmed histologically. The technique also allowed for the differentiation of a gallstone in the cystic duct from a possible tumorous lesion. In the pancreatic duct, however, the guided biopsy technique did not aid in the differential diagnosis of benign or malignant lesions. In three out of four cases of verified pancreatic cancer, the histological diagnosis was false-negative, probably because the tumor mass was not reached. An advantage of the guided biopsy over cytological examination is that the intraluminal forceps can biopsy lesions involving infiltration of the deeper layers of the lumen wall or superficial spreading over the surface of the ducts; the criteria of malignancy rest on the manner of proliferation rather than on the nature of the individual cell. The biopsy specimens are very small and need an exact preparation. Orientation of the specimen in the paraffin block and the direction of section are critical factors for proper evaluation, as is a knowledge of the exact location from which the specimen was obtained.

GASTROINTESTINAL DISEASES

ESOPHAGUS

2059 TECHNIQUE AND EXPERIENCE WITH 24-HOUR ESOPHAGEAL pH MONITORING IN CHILDREN.

(Eng.) Hill, J. L.; Pelligrini, C. A.; Burrington, J. D.; Reyes, H. M.; DeMeester, T. R. (22 S. Greene St., Baltimore, MD 21201). *J. Pediatr. Surg.* 12(6):877-887; 1977.

A 24-hr pH esophageal monitoring technique was used to evaluate gastroesophageal reflux in two normal control children and in five children with abnormal gastroesophageal reflux. The technique involved positioning a glass pH electrode through the nasopharynx 3 cm proximal to the distal esophageal sphincter. A second reference probe was wrapped on the nondominant forearm of the subject. For the two normal controls, values for the total number of refluxes (9 and 53, resp.); the percentage of time that the pH was less than 4 (0.84% and 2.1%, resp.); the number of refluxes greater than 5 min in duration (0 and 1, resp.); the percentage of reflux time in the supine (0.77% and 1.1%, resp.), upright (0.3% and 1.4%, resp.), and prone positions (1.53% and 1.8%, resp.); and the longest episode in minutes (3 and 16, resp.) revealed considerable variation regardless of age and maturation. A 9-month-old girl suffered frequent episodes of regurgitation and vomiting and underwent a Nissen fundoplication after having her narrowed distal esophagus dilated three times. Pre- and postoperative values were, resp., 131 and 28 for the total number of refluxes; 14% and 0.84% for the percentage of time the pH was less than 4.0; 8 and 0 for the number of refluxes greater than 5 min in duration; 4.14% and 0.54% for the percentage of reflux time in the supine position; 24% and 1.12% for the percentage of reflux time in the upright position; and 22 and 1 min for the longest episode. It is concluded that 24-hr esophageal monitoring has better objectivity, precision, sensitivity, and reliability than contrast studies, endoscopy, esophageal biopsy, acid perfusion, or acid reflux tests. The 24-hr pH monitoring technique assists in the evaluation of sphincter maturation, pulmonary disease, and the significance of body position.

2060 CONGENITAL CRICOPHARYNGEAL ACHALASIA.

(Eng.) Reichert, T. J.; Bluestone, C. D.; Sieber, W. K.; Stool, S. E.; Sieber, A. M. (Children's Hosp. Pittsburgh, 125 DeSoto St., Pittsburgh, PA 15213). *Ann. Otol. Rhinol. Laryngol.* 86(5, Part 1):603-610; 1977.

Anatomical features, physiological aspects, methods of evaluation, clinical course, and recommendations for management are presented in 15 infants with congenital cricopharyngeal achalasia. Although most of the patients had symptoms at birth, the diagnosis was frequently not confirmed until later in the first year of life. While four of the infants had only cricopharyngeal achalasia, 11 had associated diseases related to the central nervous system. Those patients without associated diseases improved spontaneously with conservative management; most of the infants with other abnormalities also improved, although their clinical progress was slower and more complicated. In three patients, the symptoms were persistent, and there were two deaths related to associated diseases. Cricopharyngeal myotomy was carried out in two children with only moderate improvement in symptoms. Congenital cricopharyngeal achalasia is more common than formerly recognized. When suspected, an esophagram with tele- or cineradiography is essential to confirm the diagnosis. Esophageal motility studies will quantify changes and also evaluate lower esophageal dysfunction not easily identified on esophagrams.

2061 LOWER ESOPHAGEAL SPHINCTER DYSFUNCTION IN ESOPHAGEAL ATRESIA: NOCTURNAL REGURGITATION AND ASPIRATION PNEUMONIA.

(Eng.) Shermeta, D. W.; Whitington, P. F.; Seto, D. S.; Haller, J. A. (Johns Hopkins Univ. Sch. Medicine, 601 N. Broadway, Baltimore, MD 21205). *J. Pediatr. Surg.* 12(6):871-876; 1977.

Esophageal manometry was used to assess esophageal function after successful repair of esophageal atresia and tracheoesophageal fistula (TEF) in six randomly selected patients and in two patients with recurrent pneumonitis. Esophageal peristalsis was irregular in every patient, and two patients with severe regurgitation and recurrent pneumonitis had marked gastroesophageal reflux. Six patients had normal lower esophageal sphincter (LES) function, with a resting pressure greater than 15 mm of Hg and uniform relaxation with swallowing. The two patients with recurrent pneumonitis, severe regurgitation, and demonstrable gastroesophageal reflux had abnormal LES function, with resting LES pressures of 0 and 11 mm Hg. The patient with the 11-mm Hg gradient had a Nissen fundoplication at the age of 1 yr; his LES did not relax with swallowing, suggesting that this pressure was the result of the surgically created sphincter. Bethanechol (0.075 mg/kg, i.m.) was administered to the two patients with subnormal LES pressure, and the LES function was normal 10 min after drug administration. The LES resting pressure in these two patients was 35 mm Hg and relaxed to gastric pressure with swallowing in both cases. Respiratory reversal occurred proximal to the LES, confirming the absence of hiatal hernia in both children. Esophageal manometry was performed at 1 week and at 9 months after the beginning of bethanechol therapy in one child. At 1 week, the resting LES pressure after p.o. bethanechol (1.25 mg) was 30 mm Hg, and relaxation was normal. At 9 months, the LES pressure before bethanechol was 0 mm Hg; after i.m. bethanechol it was 35 mm Hg, and relaxation was normal. These studies suggest that recurrent pneumonias after repair of TEF with esophageal atresia may be due to an incompetent LES in some children who have esophageal reflux and aspiration. They also demonstrate the usefulness of bethanechol in managing the patient until surgical repair can be carried out.

2062 GASTRIN CONTENT OF COLUMNAR MUCOSA LINING THE LOWER (BARRETT'S) ESOPHAGUS.

(Eng.) Dalton, M. D.; McGuigan, J. E.; Camp, R. C.; Goyal, R. K. (Univ. Texas Southwestern Medical Sch., 5323 Harry Hines Blvd., Dallas, TX 75235). *Am. J. Dig. Dis.* 22(11):970-972; 1977.

Tissue gastrin was determined in 36 biopsy specimens from the esophagus and 35 from the stomach in 12 patients with Barrett's esophagus. Histology of the mucosa from the area adjacent to the biopsy sites was also examined. Esophageal biopsies were obtained from three different sites in each patient. The gastric biopsies were obtained from the antrum, fundus, and the area just distal to the lower border of the lower esophageal sphincter. The columnar mucosa lining the esophagus was of three distinct types: fundic, transitional (cardiac), or specialized. None of these epithelia or the squamous epithelium showed any detectable gastrin. In contrast, antral mucosa had a very high gastrin content (4,870 ± 1,230 pg/mg); smaller amounts of gastrin were detected in duodenal epithelium (710 and 480 pg/ml in two specimens, resp.), whereas fundic mucosa contained very small amounts of gastrin. These results favor a metaplastic origin of Barrett's esophagus.

2063 PALLIATIVE INTUBATION AND RESECTION IN OESOPHAGEAL CARCINOMA.

(Eng.) Angorn, I. B.; Hegarty, M. M.; Baker, L. W. (Dept. Surgery, Univ. Natal, Durban, South Africa). *J. R. Coll. Surg. Edinb.* 22(5):325-330; 1977.

The results of intubation with Celestin tubes or of resection for the palliation of dysphagia in squamous esophageal carcinoma were analyzed in 140 patients. Tumor characteristics that could influence the success of intubation, *viz*, site, length, the presence of total dysphagia, histopathological grading, esophageal axis disturbance, and respiratory tree involvement were evaluated. Intubation was successful in 71% of patients if the tumor was situated between the thoracic inlet and tracheal bifurcation, but in only 47% of patients with lesions more distally situated. The presence of esophageal axis disturbance and esophago-respiratory fistula adversely affected intubation. A randomized trial of intubation *versus* resection for lower esophageal tumors revealed significantly better results for resection. It is recommended that intubation be reserved for upper tumors, and palliative resection be considered for lower tumors.

2064 CRICOPHARYNGEAL MYOTOMY AS A METHOD OF TREATING CRICOPHARYNGEAL DYSPHAGIA SECONDARY TO GASTROESOPHAGEAL REFLUX.

(Eng.) Henderson, R. D.; Marryatt, G. (Women's Coll. Hosp., Toronto, Ontario M5S 1B2, Canada). *J. Thorac. Cardiovasc. Surg.* 74(5):721-725; 1977.

Experience with cricopharyngeal myotomy for the treatment of pharyngoesophageal dysphagia secondary to gastroesophageal reflux during a 5-yr period is presented. Myotomy was used in 2 patients whose only symptom was dysphagia, in 3 patients too debilitated for major surgery, and in 15 patients with persistent pharyngoesophageal dysphagia following hiatal hernia repair. All were studied by barium esophagogram, endoscopy, and manometry. Radiologic aspiration of barium was apparent in 5 of 19 patients. High-speed manometric tracings showed intermittent cricopharyngeal incoordination in the six consecutive patients most recently studied. This finding of incoordination was present in 38 patients with reflux and in all with major cricopharyngeal symptoms. Myotomy was effective in relieving symptoms in patients in whom this was the only reflux symptom and in the patients too debilitated for major surgery. Good symptomatic improvement was obtained in nine patients with persistent dysphagia following hernia repair, but in three, relief was partial, with persistent symptoms being secondary to distal esophageal obstruction. Investigation is necessary to exclude other causes of dysphagia. However, with careful selection, myotomy has proved to be an effective method of treatment.

2065 SYMPTOMATIC REFLUX ESOPHAGITIS: A DOUBLE-BLIND CONTROLLED COMPARISON OF ANTACIDS AND ALGINATE.

(Eng.) Graham, D. Y.; Lanza, F.; Dorsch, E. R. (Baylor Coll. Medicine, 1200 Moursund Ave., Houston, TX 77030). *Curr. Ther. Res.* 22(5): 653-658; 1977.

A 4-week double-blind study of the effectiveness of antacid tablets and of alginate-containing tablets was undertaken in 41 patients with esophagitis. The patients received either (a) a preparation containing stoichiometric amounts of alginic acid, sodium bicarbonate, and aluminum hydroxide dried gel (80 mg) and magnesium trisilicate (20 mg) or (b) an antacid containing co-dried aluminum hydroxide and magnesium carbonate (203.1 mg), manitol (101.53 mg), dextrose (1,159.74 mg), sucrose (101.53 mg), methyl cellulose (10.12 mg), calcium stearate (16.0 mg), and flavoring. Both treatment regimens produced significant improvement in severity and frequency of heartburn and in reversal of endoscopic findings of mucosal friability or erosions. Approximately 75% of both groups achieved complete healing of endoscopic manifestations of esophagitis. Antacid yielded better symptomatic relief, although the differences between the groups were not statistically significant. As the effectiveness of the two agents is probably dependent upon different mechanisms, it is possible that a combination of these agents would produce a synergistic effect and provide an ideal therapeutic regimen.

2066 STUDIES OF ESOPHAGEAL EPITHELIAL CELL PROLIFERATION IN PATIENTS WITH REFLUX ESOPHAGITIS.

(Eng.) Livstone, E. M.; Sheahan, D. G.; Behar, J. (Yale Univ. Sch. Medicine, 333 Cedar St., New Haven, CT 06510). *Gastroenterology* 73(6): 1315-1319; 1977.

The *in vitro* proliferative activity of the basal zone of the esophagus was studied in suction biopsy specimens from 7 normal subjects, 19 patients with medically treated esophagitis, and 8 patients who had previously undergone anterior fundoplication. In the 10 patients with severe esophagitis, the basal zone showed a significantly elevated [^{3}H]thymidine labeling index (14.4 ± 2.2%) in contrast to that of mild esophagitis patients (6.4 ± 0.6%) and that of normal subjects (6.1 ± 0.7%, $p<0.05$). When esophagitis was associated with mucosal lesions at endoscopy, the labeling index was higher than that seen in esophagitis patients without endoscopic abnormalities ($p<0.05$). Significantly increased thymidine labeling was found only in patients with the most severe changes of papillary length or basal layer thickening. It is concluded that there is an increased basal zone uptake of [^{3}H]thymidine in severe esophagitis, which suggests increased cell turnover as the mechanism for basal zone hyperplasia. Present techniques for measuring mucosal uptake of [^{3}H]thymidine, however, do not permit the distinction of mild degrees of esophagitis from normal epithelium.

2067 COMPLICATIONS AND FAILINGS OF THE COMBINED COLLIS-BELSEY OPERATION. (Eng.) Orringer, M. B.; Sloan, H. (C7175 Univ. Hosp., Ann Arbor, MI 48109). *J. Thorac. Cardiovasc. Surg.* 74(5):726-735; 1977.

Complications and early follow-up data are presented on 83 patients who underwent the Collis-Belsey operation (gastroplasty combined with hiatal hernia repair). These patients were at risk for the recurrence of reflux after standard hiatal hernia repairs. There were two postoperative deaths. Complications related to multiple operations on the lower esophagus included injury to the spleen (3 patients), gastrocutaneous fistula (2 patients), and localized ischemic necrosis of the esophagus (2 patients). There were two esophageal perforations. In 4 of 15 patients, the combination of esophagomyotomy and the Collis-Belsey operation produced functional esophageal obstruction. Three patients experienced late major lower esophageal bleeding from ulceration of mucosa adjacent to the gastroplasty tube; two of these patients have no demonstrable gastroesophageal reflux. In addition to postoperative interviews and barium swallows, 77 patients were evaluated with esophageal manometry and acid reflux testing. After an average follow-up of 12 months, 19% have symptomatic reflux, but 30% have moderate-to-severe reflux with pH reflux testing. The recent popularity of the combined Collis-Belsey operation to reduce the incidence of recurrent gastroesophageal reflux should be tempered by continued, cautious, objective assessment of its long-term results.

2068 INTRAOPERATIVE AND POSTOPERATIVE ESOPHAGEAL MANOMETRIC FINDINGS WITH COLLIS GASTROPLASTY AND BELSEY HIATAL HERNIA REPAIR FOR GASTROESOPHAGEAL REFLUX. (Eng.) Cooper, J. D.; Hill, S. S.; Nelems, J. M.; Pearson, F. G. (Toronto General Hosp., Toronto, Ontario M5G 1L7, Canada). *J. Thorac. Cardiovasc. Surg.* 74(5):744-751; 1977.

The effect of gastroplasty and Belsey repair on intraluminal pressure changes in the gastroplasty and lower esophagus was studied in 11 patients. Manometry was performed preoperatively, intraoperatively, and postoperatively. In each case, the gastroplasty segment of the esophagus was found to function as a high pressure zone (HPZ). The pressure in this zone further increased following fundoplication. It could be diminished by the i.v. administration of hyoscine-*N*-butylbromide and augmented with i.v. pentagastrin. The original lower esophageal sphincter in most instances was included in the upper segment of the gastroplasty tube, but the entire length of the gastroplasty tube functioned as an HPZ, and pressures in the tube were considerably higher than those originally present in the lower esophageal sphincter. These studies provide a physiological basis for the effectiveness of gastroplasty and fundoplication.

2069 ABNORMALITIES OF GASTRIC EMPTYING AND PYLORIC REFLUX IN UNCOMPLICATED HIATUS HERNIA. (Eng.) Donovan, I. A.; Harding, L. K.; Keighley, M. R. B.; Griffin, D. W.; Collis, J. L. (General Hosp., Birmingham, England). *Br. J. Surg.* 64(12):847-848; 1977.

The rate of gastric emptying of solid and liquid meals was studied in 10 patients with hiatal hernia, 22 patients with duodenal ulcer, and 8 controls, using an external scanning technique. Pyloric reflux was studied by a radiological technique. There was a significant delay in the emptying of both solid and liquid meals in the patients with hiatal hernia compared with both the duodenal ulcer patients (solid meals $p<0.01$, liquid meals $p<0.025$) and with normal controls (solid meals $p<0.05$, liquid meals $p<0.001$). Duodenogastric reflux was observed in 35% of hiatal hernia patients compared with 24% of duodenal ulcer patients and 0% of the controls. The findings of delayed gastric emptying and an increased incidence of duodenogastric reflux suggest a possible cause for the symptoms.

2070 ESOPHAGEAL HISTOLOGY IN GASTROESOPHAGEAL REFLUX: MORPHOMETRIC FINDINGS IN SUCTION BIOPSIES. (Eng.) Seefeld, U.; Krejs, G. J.; Siebenmann, R. E.; Blum, A. L. (Stadtspital Triemli, 8063 Zurich, Switzerland). *Am. J. Dig. Dis.* 22(11):956-964; 1977.

To study the histological appearance of esophageal damage produced by reflux, esophageal suction biopsies were taken in 24 subjects with proven gastroesophageal reflux, 12 subjects with suspected reflux, and 20 healthy controls. Sixty-two percent of the patients with proven reflux, 33% of the patients with suspected reflux, and 10% of the controls had neutrophilic and/or eosinophilic granulocytes in the lamina propria. Lymphocytes, plasma cells, and basophilic granulocytes were shown to be constituents of the normal esophageal mucosa. All epithelial dimensions showed marked individual variations in reflux patients and controls. The relative length of stromal papillae, as expressed in percent of total epithelial thickness, showed a linear correlation with relative basal cell thickness and an indirect linear correlation with epithelial thickness. Elongation of stromal papillae in proven reflux could only be demonstrated by arbitrary retrospective stratification of the data. Hyperplasia of the basal zone and thinning of the epithelium were not observed in the reflux patients. It is concluded that granulocytic infiltrates and not epithelial alterations are the most prominent histological finding in gastroesophageal reflux.

2071 THE EFFECT OF METOCLOPRAMIDE ON GASTRO-OESOPHAGEAL REFLUX. (Eng.) Pflucke, F.; Arendt, R. (Clinic Internal Medicine, Wilhelm Pieck Univ., Ernst Hendemann Strasse, DDR-25 Rostock, E. Germany). *Tijdschr. Gastroenterol.* 20(3):155-162; 1977.

Recordings of esophageal pH values in 17 patients with gastroesophageal reflux revealed that the i.v. administration of 0.15 mg/kg of metoclopramide significantly ($p<0.01$) reduced reflux duration and frequency. Reflux phenomena disappeared completely in 8 of the 17 patients, and the reflux frequency was reduced in 16 patients. The effect was seen clearly after 10-20 min and was still evident after 2 hr. The mean total reflux duration dropped from 31.9%/hr before metoclopramide treatment to 14.6%/hr after drug treatment. The mean reflux frequencies before and after drug treatment were 6.3/hr and 2.3/hr, resp. The effect of metoclopramide on reflux duration and frequency is probably dependent on the presence of a lower esophageal sphincter. Thus, if the sphincter region has been surgically removed, no considerable reflux-reducing effect can be expected.

2072 POSTPRANDIAL GASTRO-OESOPHAGEAL REFLUX IN HEALTHY PEOPLE. (Eng.) Kaye, M. D. (Univ. Vermont Coll. Medicine, Burlington, VT). *Gut* 18(9):709-712; 1977.

Studies were carried out to determine whether or not the normal lower esophageal sphincter remains continuously competent under physiological conditions, in an effort to provide a more solid basis for the definition of incompetence of the lower esophageal sphincter and to devise a test applicable to the investigation of physiological and pharmacological influences upon its competence. Distal esophageal pH was monitored for 3 hr after a standard meal in 10 young healthy subjects without symptoms of gastro-esophageal reflux. Episodes of reflux occurred in nine subjects, and in five, the esophageal pH was less than 5 for between 11% and 75% of the first postprandial hour. Intermittent incompetence of the lower esophageal sphincter after food must, therefore, be regarded as a normal phenomenon. The method described would be suitable for the evaluation of agents believed to weaken or to strengthen the lower esophageal sphincter.

2073 DIFFUSE SPASM OF THE ESOPHAGUS: CLINICAL, MANOMETRIC, AND SURGICAL CONSIDERATIONS. (Eng.) Leonardi, H. K.; Shea, J. A.; Crozier, R. E.; Ellis, F. H., Jr. (Lahey Clinic Foundation, 605 Commonwealth Ave., Boston, MA 02215). *J. Thorac. Cardiovasc. Surg.* 74(5):736-743; 1977.

Pre- and postoperative clinical, manometric, and roentgenographic findings are presented for 11 patients who underwent extended esophagomyotomy for diffuse spasm of the esophagus (DSE). Preoperative manometry performed in all patients disclosed a mean deglutitive pressure of 70 mm Hg in the diseased areas and indicated the required length of myotomy. The lower esophageal sphincter (LES) was within normal limits in most instances, with a mean amplitude of 20 mm Hg, and its exclusion from the myotomy eliminated the need for additional antireflux procedures. Postoperative manometry in 10 patients disclosed a 70% reduction in deglutitive pressures in the myotomized segments, and the mean LES amplitude of 13 mm Hg remained within the normal range (10-20 mm Hg). Ten of the 11 patients were clinically improved, and postoperative reflux developed in only 1 patient. These results support the continued use of extended esophagomyotomy in selected patients with DSE and suggest that exclusion of the LES from the myotomy affords satisfactory antireflux protection without ancillary sphincter-enhancing maneuvers.

2074 FURTHER EVALUATION OF THE SUGIURA PROCEDURE IN THE TREATMENT OF ESOPHAGEAL VARICES. (Eng.) Sugiura, M.; Futagawa, S. (Second Dept. Surgery, Univ. Tokyo, Hongo 7-3-1, Bunkyoku, Tokyo, Japan). *Arch. Surg.* 112(11):1317-1321; 1977.

The results of esophageal transection with paraesophagogastric devascularization (the Sugiura procedure) for bleeding esophageal varices were evaluated in 276 patients who underwent the procedure between 1967 and the present. Sixty procedures were prophylactic, 164 were elective, and 52 were emergency procedures. The age distribution was from 9 months to 74 yr. The origin was cirrhosis in 191 patients, fibrosis in 59, extrahepatic portal vein occlusion in 18, hepatoma in 5, schistosomiasis in 1, Budd-Chiari syndrome in 1, and carcinoma of the pancreas in 1 patient. The mortality within 1 month of surgery was 5.0% in prophylactic cases, 1.8% in elective cases, and 11.5% in emergency cases (mean, 4.3%). The 7-yr survival rate was 83%. There was an obvious positive correlation between survival rate and stage of the disease. Ninety-five percent of class A (Child's classification) and 87% of class B are alive, but only 59% of class C patients are alive at the present. Six patients had recurrences of varices for a recurrence rate of 2.3%, of whom four had esophageal bleeding. It may be that recurrence of varices occurred due to incomplete devascularization of the esophagus at the diaphragm because of the necessity of two-stage operations in poor-risk patients. All survivors are free from encephalopathy. This study reconfirms that the Sugiura method is safe and effective in controlling esophageal variceal bleeding without compromising epatic function.

111 GASTRIC BEZOAR FORMATION SECONDARY TO GASTROPARESIS DIABETICORUM. (Eng.) Brady, . G.; Richardson, R. (Univ. Kentucky Medical Cener, Lexington, KY 40506). *Arch. Intern. Med.* 137 12):1729; 1977.

case of gastric phytobezoar formation that was econdary to diabetic autonomic neuropathy is reorted. Greatly impaired gastric emptying was ocumented in this case by the administration of radiolabeled meal. The patient's half-time of astric emptying was 282 min. The i.v. and p.o. dministration of metoclopramide hydrochloride 10 mg, 4 x/day, p.o.) completely corrected the atient's gastric motility disturbance. Diabetic utonomic neuropathy may result in delayed gastric mptying and gastric retention.

112 STUDIES ON SERUM GASTRIN OF THE PATIENTS WITH GASTRIC CANCER. (Eng.) Itoh, T.; atsuta, M.; Tamura, H.; Yamamura, H.; Iwanaga, T. Center for Adult Diseases, 1 Chome, Nakamichi, igashinari-ku, Osaka 537, Japan). *Am. J. Gastronterol.* 68(1):56-63; 1977.

n 46 patients with gastric cancer who were to ndergo gastrectomy, the fasting serum gastrin oncentration in the peripheral vein was estimated y radioimmunoassay. Blood samples were also ollected from the gastric veins and artery during he operations. These gastrin values were compared ith morphological findings in the resected stomach. o significant difference in serum gastrin conentration was found between the patients with astric cancer and 11 normal subjects. In the atients with mucosal atrophy in the oxyntic land area but with no atrophy in the pyloric land area, however, a significant increase in erum gastrin concentration ($p<0.05$) was observed. n cases in which fundal atrophy was accompanied y atrophy in the pyloric gland area, this inrease was not observed. The gastrin content of he cancerous tissue was negligible. These reults indicate that the increase in serum gastrin oncentration in some patients with gastric cancer ight be due to the associated atrophy of the xyntic glands.

2163 GASTRIC CYCLIC NUCLEOTIDE CONCENTRATION IN HEALTH AND DISEASE. RESPONSE TO SECRETAGOGUES AND ROLE OF CIRCULATING GASTRIN AND INTRAGASTRIC ACID SECRETION. (Eng.) Levine, R. A.; Schwartzel, E. H., Jr.; Bachman, S.; Talev, J. N. (Upstate Medical Center, 750 East Adams St., Syracuse, NY 13210). *Gastroenterology* 73(4, Part 1): 737-745; 1977.

Cyclic AMP and cyclic guanosine monophosphate (GMP) concentrations were measured in suction biopsy specimens of gastric fundic and antral mucosa and in gastric juice in response to maximum stimulation by histamine (0.015 mg/kg/hr), betazole (1.5 mg/kg), and pentagastrin (6 μg/kg) in 14 normogastrinemic healthy subjects, in 46 patients with dyspepsia or peptic ulcer (PU) disease and normal serum gastrin levels, and in 14 patients with hypergastrinemia (8 with pernicious anemia [PA], 3 with Zollinger-Ellison [ZE] syndrome, and 3 with gastric carcinoma). No regional differences were noted in unstimulated gastric antral or fundic cyclic nucleotide content in normal subjects or patients. During secretagogue stimulation, no significant changes in cyclic nucleotide concentrations were observed in antral or fundic mucosa of healthy subjects or patients. During basal hourly secretion, cyclic nucleotide concentration and output in gastric juice were relatively constant, suggesting a steady state of secretion. After secretagogue stimulation, the concentrations of cyclic AMP and cyclic GMP were reduced by at least 50% and correlated with the increased parietal volume output, suggesting a dilutional effect. There was no significant change in gastric juice cyclic nucleotide output except in PU subjects after betazole stimulation, in whom cyclic AMP production increased almost twofold. This change in gastric juice cyclic AMP concentration was proportional to a greater parietal volume flow and did not reflect intracellular mucosal events. Similarly, a decreased concentration of cyclic AMP in the basal and stimulated gastric juice of ZE patients and a reduced cyclic AMP output in PA patients was also proportional to volume flow. The presence of cyclic AMP in unstimulated gastric juice in PA suggests, in part, a nonparietal origin for cyclic AMP, probably derived from interstitial fluid secretion or transmucosal exudation from plasma. It is concluded that intra- or extracellular gastric cyclic AMP or cyclic GMP concentrations are not modulated by secretagogue stimulation, circulating high gastrin levels, alteration in intraluminal pH, or increasing age. These studies fail to implicate cyclic nucleotides as intracellular mediators of stimulated gastric acid secretion in healthy subjects, PU disease PA, ZE syndrome or gastric carcinoma.

2164 GASTRIC SECRETION AND EMPTYING AFTER ORDINARY MEALS IN DUODENAL ULCER. (Eng.) Malagelada, J. R.; Longstreth, G. F.; Deering, T. B.; Summerskill, W. H. J.; Go, V. L. W. (Mayo Clinic, Rochester, MN 55901). *Gastroenterology* 73(5):989-994; 1977.

The gastric response to an ordinary solid-liquid meal was studied in 12 patients with active duodenal ulcer and 8 healthy volunteers, using gastric and duodenal markers to quantify acid, pepsin, and volume outputs in response to the meal, without manipulating intragastric pH. Intragastric volume, rate of gastric emptying, delivery of acid into the duodenum, and serum gastrin response were also measured simultaneously. On a separate day, peak acid output in response to betazole (1.5 mg/kg, s.c.) was determined. There was an inappropriately prolonged gastric secretory response to meals in duodenal ulcer disease, without a concomitant increase in peak postprandial secretory rates or an increase in serum immunoreactive gastrin levels. The stomach in duodenal ulcer disease did not "retain" the additional acid secreted in the later postprandial period, and abnormally high rates of acid delivery into the duodenum occurred. These data are consistent with a dual defect in the duodenal mechanisms regulating both acid secretion and acid delivery into the duodenum.

2165 ACID AND ENDOCRINE RESPONSES TO MEALS VARYING IN pH IN NORMAL AND DUODENAL ULCER SUBJECTS. (Eng.) Thompson, J. C.; Swierczek, J. S. (Univ. Texas Medical Branch, Galveston, TX 77550). *Ann. Surg.* 186(4):541-548; 1977.

Gastric acid, gastrin, gastric inhibitory peptide (GIP), and secretin responses to meals (varying in pH) were compared in 12 normal subjects and 9 duodenal ulcer patients. Acid secretion was measured by an intragastric titration method that allows actual measurement of acid response to food within the stomach (10% amino acid meal, adjusted to various pH levels, 7-1.5). Blood samples were collected at each pH level for radioimmunoassay of gastrin, secretin, and GIP. Gastric acid and gastrin responses to the amino acid meal (AAM) were significantly greater in duodenal ulcer patients than in normal subjects. In duodenal ulcer patients, acid response to AAM at pH 7 or 5.5 reached 82% of Histolog maximum. Decreasing the pH of the meal resulted in a stepwise reduction in both acid secretion and gastrin in normal subjects and duodenal ulcer patients. At pH 1.5, acid inhibition was complete, but gastrin inhibition was partial. Secretin concentration increased significantly at pH 1.5; there was no difference in secretin release between the groups. Plasma GIP was highest at pH 7 in all individuals. Use of a marker substance showed 80% recovery of AAM at pH 7-4; below pH 4, recovery rose to about 90%. It is concluded that gastric acid and gastrin release are pH-dependent in normal subjects and duodenal ulcer patients. Inhibition of gastric secretion by acidified meals is associated with a pH-dependent suppression of gastrin and GIP levels and an elevation of plasma secretin. This study confirms increased acid and gastrin responses in duodenal ulcer patients but shows no evidence of defective feedback inhibition of gastric secretion and gastrin release.

2166 THE EFFECT OF GASTRIC DISTENSION ON THE SECRETION OF ACID AND PEPSIN BY PATIENTS WITH DUODENAL ULCER. (Eng.) Saunders, J. H. B.; Wormsley, K. G. (Ninewells Hosp., Dundee DD2 1UB, Scotland). *Acta Hepatogastroenterol.* 24(4):271-277; 1977.

The effect of gastric distention on the secretion of acid and pepsin was studied in 24 patients with chronic duodenal ulcers to determine the presence of "neural tone." Basal secretion was collected for 1 hr from 14 patients who were successively insufflated with 50, 100, and 200 ml of air by a rubber balloon (each distention was maintained for 30 min). Gastric contents were collected every 15 min and the acid and pepsin levels were assayed. Nine of these patients were subjected to a second test and were insufflated with 200 ml of air for 1 hr after collection of a 1-hr basal secretion. Seven other patients received only the second test. Acid and pepsin secretion after graded distention displayed similar patterns. The mean acid output of the 14 subjects was 2.4 mmol/30 min, and was 3.4 (42% greater than basal values), 2.6, and 5.5 mmol/30 min (129%) in response to 50, 100, and 200 ml of air, resp. Pepsin output was increased by 31 and 79% in response to 50 and 200 ml of air, resp. Acid and pepsin secretion in response to prolonged distention with 200 ml of air was similar to that observed with graded distention; there was a 59% increase in acid concentration, a 173% increase in acid output, and a 151% increase in pepsin output. In a third test schedule, pentagastrin was infused 1 hr before distention with 200 ml of air. Low doses (0.02 μg/kg body weight/hr, 12 subjects) produced an acid response 83% greater, and a pepsin response 43% greater, than basal values. A high dose of pentagastrin (2 μg/kg/hr) had no significant effect on acid or pepsin output. Thus, distention stimulated gastric secretion in a manner similar to, but weaker than, pentagastrin. The results suggest that gastric distention does not produce a "neural" stimulus for the gastric secretion of acid or pepsin in man.

2167 IS THERE AN OXYNTOPYLORIC REFLEX FOR RELEASE OF GASTRIN IN MAN? (Eng.) Grotzinger, U.; Rehfeld, J. F.; Olbe, L. (Kantonsspital, CH-4004 Basel, Switzerland). *Gastroenterology* 73(4, Part 1):753-757; 1977.

In order to determine whether gastrin released by an oxyntopyloric reflex contributes to acid secretion, plasma gastrin concentrations and gastric acid output were measured during graded balloon distention of the gastric fundus and body in 20 patients with duodenal ulcer. Acid output rose stepwise with increasing distention volumes, but plasma gastrin remained unchanged. During intragastric neutralization in five subjects, fundic distention did not elicit a significant rise in plasma gastrin, whereas the acid response was similar to that observed in the control study when the gastric contents were acid. In eight patients, proximal gastric vagotomy profoundly suppressed the acid response to fundic distention. Basal plasma gastrin concentrations were elevated after vagotomy, but were unchanged during graded fundic distention. The results suggest that neural reflex activation of the oxyntic glands is the main mechanism by which fundic distention stimulates acid secretion in man. The failure of fundic distention to release gastrin does not completely rule out the existence of an oxyntopyloric distention reflex for gastrin release in man. Fundic distention in man seems to both stimulate acid secretion and induce an inhibitory mechanism acting on acid secretion. The authors suggest that this inhibitory mechanism may also mask the effect of an oxyntopyloric reflex for gastrin release. The present study and earlier work suggest that, in man, distention of the stomach is a poor stimulus for release of gastrin, regardless of whether the pyloric or the oxyntic gland area, or both, are distended.

2168 THE ACTION OF ANTACIDS ON SERUM GASTRIN CONCENTRATIONS IN MAN. (Eng.) Feurle, G. E. (Medizinische Universitats-Poliklinik, Hospitalstrasse 3, D-6900 Heidelberg, W. Germany). *Klin. Wochenschr.* 55(21):1039-1042; 1977.

To investigate the effect of antacids on serum gastrin concentration, the effects of two doses of NaCl and $NaHCO_3$, as well as of $AlCl_3$ (all three substances, 30 ml, 8 g/100 ml) and $Al(OH)_3$ (30 ml, 5.4 g/100 ml), resp., on serum gastrin concentrations and intragastric pH were compared in 27 duodenal ulcer patients. In addition, the effect of one dose of an AlPO containing commercial antacid on serum gastrin concentration and intragastric pH was studied in duodenal ulcer patients and in seven controls. Care was taken to induce swallowing at the times that the substances were given through an orogastric tube. Antacids elicited significantly greater gastrin responses than their nonbuffering chloride compounds ($p<0.05$), and the rise in gastrin level after a single dose of antacid was small but significant ($p<0.05$) in duodenal ulcer patients and insignificant in nonulcer controls. Several factors such as rising intragastric pH, individual responsiveness, duodenal ulcer state, vagal influences, and the participating ions, and their amount contribute to the rise in gastrin levels after antacids.

2169 CARBENOXOLONE SODIUM CAPSULES IN THE TREATMENT OF DUODENAL ULCER: AN ENDOSCOPIC CONTROLLED TRIAL. (Eng.) Sahel, J.; Sarles, H.; Boisson, J.; Bonnet-Eymard, J.; Cornet, A.; Delmont, J.; *et al.* (U-31 INSERM, Marseille, France). *Gut* 18(9):717-720; 1977.

The results of carbenoxolone treatment for duodenal ulcer were assessed in a multicenter controlled trial of 86 patients with duodenal ulcer who were treated with carbenoxolone capsules (50 mg, q.i.d. for 6 weeks) or a placebo. Sixty-nine patients underwent endoscopy at the beginning and end of the treatment. Symptomatic responses and endoscopic improvement were significantly greater in those receiving the active preparation than in those receiving the control capsules; complete, endoscopically assessed, healing was achieved in 65% and 20%, resp., of individuals who underwent endoscopy, after 6 weeks of treatment. Side-effects of salt and water retention or hypokalemia were noted in over one-fourth of those receiving the carbenoxolone capsules, but none of the adverse effects was severe enough to necessitate withdrawal of treatment. The results show that treatment with carbenoxolone sodium capsules accelerates the healing of duodenal ulcers and that this healing is paralleled by the remission of symptoms.

2170 CIMETIDINE FOR DUODENAL ULCERATION IN PATIENTS UNDERGOING HAEMODIALYSIS. (Eng.) Doherty, C. C.; O'Connor, F. A.; Buchanan, K. D.; McGeown, M. G. (Belfast City Hosp., Belfast BT9 7AB, Northern Ireland). *Br. Med. J.* 2(6101):1506-1508; 1977.

The effect of cimetidine was assessed in the treatment of nine patients with acid hypersecretion and endoscopically diagnosed duodenal ulceration who were undergoing hemodialysis. The patients obtained good pain relief and suffered no serious side-effects. Both basal and stimulated acid output fell considerably, and the plasma gastrin response to food increased during treatment. Two patients with recurrent vomiting during hemodialysis had a striking response to cimetidine, which suggested that such vomiting may be acid-mediated in some patients. These preliminary results suggest that cimetidine may prove to be an advance in the management of peptic ulcer in uremic patients.

2171 DOUBLE-BLIND CLINICAL TRIAL ON GASTRODUODENAL ULCER HEALING WITH PROSTAGLANDIN E_2 ANALOGUES. (Eng.) Gibinski, K.; Rybicka, J.; Mikos, E.; Nowak, A. (Silesian Sch. Medicine, Katowice, Poland). *Gut* 18(8):636-639; 1977.

Seventy-seven patients with gastroduodenal ulcer were treated p.o. with two methyl-prostaglandin E_2 analogues (m-PGE_2) in a double-blind clinical trial. Each of three groups was given 15 S-15 methyl PGE_2 methyl ester (1.5 μg/kg), 15 R-15 methyl PGE_2 methyl ester (2 μg/kg), and placebo, resp. Both forms of m-PGE_2 analogues appeared to reduce gastric acid secretion ($p<0.01$ for 15 R-15 methyl PGE methyl ester; $p<0.001$ for 15 S-15 methyl PGE_2 methyl ester), to shorten ulcer healing ($p<0.001$ for 15 S-15 methyl PGE_2 methyl ester only), and also to produce some side-effects (diarrhea, vomiting, and pain), form "S" being the more potent. Prompt healing of the ulcer with these agents did not prevent the recurrence of the disease. As the serum gastrin response to a meal after m-PGE_2 administration was not reduced, this agent seems directly to affect oxynthic cells.

2172 FAT INDUCED JEJUNAL INHIBITION OF GASTRIC ACID SECRETION IN DUODENAL ULCER PATIENTS BEFORE AND AFTER TRUNCAL VAGOTOMY. (Eng.) Christiansen, J. (Glostrup Hosp., DK-2600 Glostrup, Copenhagen, Denmark). *Ann. Surg.* 186(5):573-576; 1977.

To investigate whether fat-induced jejunal inhibition of acid secretion in man is dependent on intact vagal innervation, the effect of intrajejunal infusion of a fat solution on pentagastrin-stimulated (0.5 μg/kg/hr) gastric acid secretion was studied in five duodenal ulcer patients before and 3 to 5 months after truncal vagotomy. Preoperatively, the mean acid output was reduced from 41 ± 5.2 mEq H^+/hr to 15.4 ± 1.3 mEq H^+/hr ($p<0.005$), and postoperatively from 17.4 ± 2.6 mEq H^+/hr to 12.7 ± 2.4 mEq/hr ($p<0.01$). These results demonstrate that fat-induced jejunal inhibition of gastric acid secretion is humorally mediated either in whole or in part. Furthermore, fat-induced jejunal inhibition of acid secretion in duodenal ulcer patients seems to be of the same magnitude as previously found in healthy subjects.

2173 CAUSES OF DEATH IN DUODENAL AND GASTRIC ULCER. (Eng.) Bonnevie, O. (Hvidovre Hosp., Univ. Copenhagen, 2650 Hvidovre, Denmark). *Gastroenterology* 73(5):1000-1004; 1977.

An analysis was made of 235 deaths that occurred among 1,905 patients with peptic ulcer to examine whether these patients died more frequently than expected of specific diseases. These patients constituted a random sample of the occurrence of ulcer disease in an area of Denmark comprising half a million inhabitants. The disease itself, according to the death certificate, was considered the primary cause of death in 10% of the cases; half of these had been operated on immediately before death. The other patients died more frequently than expected from the following causes: chronic bronchitis, pulmonary emphysema, lung cancer, liver cirrhosis, and pancreatic cancer. Although the comorbidity with chronic bronchitis and emphysema was especially pronounced in patients with gastric ulcer, the association with liver cirrhosis and pancreatic cancer occurred only in patients with duodenal ulcer. In women, the mortality rate attributable to cardiac and vascular diseases was lower than expected. No excess coincidence of suicide was found. Berkson's fallacy, a false association between diseases, is considered to be of much less importance as a possible explanation of the comorbidity found in the present study than in the majority of publications concerned with this question.

SMALL INTESTINE

2201 PERFUSION OF THE PROXIMAL SMALL INTESTINE WITH PEPTONE STIMULATES GASTRIC ACID SECRETION IN MAN. (Eng.) Isenberg, J. I.; Ippoliti, A. F.; Maxwell, V. L. (Veterans Admin. Wadsworth Hosp. Center, Los Angeles, CA 90073). *Gastroenterology* 73(4):746-752; 1977.

To test the hypothesis that intestinal stimulants originating in the human proximal small intestine increase gastric acid secretion, the duodenum was infused with 10% peptone (weight/volume, 400 mOsm at 2 ml/min for 4 hr in seven normal subjects and seven duodenal ulcer patients. The duodenum was perfused through a gastroduodenal tube, with two balloons straddling the pylorus to prevent duodenogastric reflux. As a control, 0.2 M NaCl was perfused into the duodenum at 2 ml/min for 4 hr on another day. The order of testing was randomized. Gastric acid secretion increased gradually during duodenal peptone perfusion and reached a peak response during the second hour of infusion. During the second hour of peptone infusion, the mean peak 30-min secretory rate was 203.8 ± 31.9 μEq/min, and during NaCl infusion, it was 87.8 ± 27.2 μEq/min ($p<0.01$). Duodenal perfusion with 0.2 N NaCl did not stimulate acid secretion. Peak 30-min secretory rate after pentagastrin (6 μg/kg, s.c.) measured on another day was 657.6 ± 50.6 μEq/min. The mean peak secretory response during the second hour of duodenal peptone perfusion was 32.6 ± 4.6% of the peak response to pentagastrin. During the time periods when gastric acid secretion was at a peak response, serum gastrin, measured at 30-min intervals throughout both tests, was unchanged from basal and NaCl control. However, the mean serum gastrin did increase slightly (approximately 16 pg/ml) but significantly in the 14 subjects during the last 90 min of duodenal peptone perfusion. Validation experiments revealed good reproducibility of the responses to duodenal peptone or NaCl perfusion, absence of an increase in gastric acid secretion or serum gastrin in response to gastric perfusion of 10% peptone in a volume equivalent to the volume that refluxed during the 4 hr of duodenal peptone perfusion, and no effect on gastric acid secretion or serum gastrin of the gastroduodenal tube with or without inflation of the duodenal and gastric balloons. These studies indicate that there is an intestinal phase of gastric acid secretion in normal man and in patients with duodenal ulcer in response to duodenal peptone perfusion, that it has a latent period of about 1 to 2 hr until the peak response is reached, and that the response is probably not primarily attributable to gastrin release.

2202 CARCINOID TUMORS, VASCULAR ELASTOSIS, AND ISCHEMIC DISEASE OF THE SMALL INTESTINE.

(Eng.) Qizilbash, A. H. (Henderson General Hosp., 711 Concession St., Hamilton, Ontario L8V 1C3 Canada). *Dis. Colon Rectum* 20(7):554-560; 1977.

The incidence of elastic vascular sclerosis and/or ischemia complicating carcinoid tumors was assessed in 21 patients, and the clinical and pathologic features of the condition are presented. Ischemic enteritis or infarction occurred in 4 of 15 patients who had carcinoid tumors of the small intestine. All four, in addition, had elastic vascular sclerosis of the mesenteric vessels. Both arteries and veins were involved, and the change occurred in the region of tumor deposit. In none of the cases was the tumor occluding the lumen of the vessels, nor was there any evidence of thrombosis. Ischemic changes occurred in two of the six patients with large intestinal carcinoid tumors, although elastic vascular sclerosis and infarction were absent. The findings suggest a direct rather than a humoral effect. It appears that cancer cells exert an inductive effect on the fibroblast or smooth muscle cell in vascular walls, causing excess production of elastic tissue.

2203 DUAL IMMUNE DEFECTS IN NONGRANULOMATOUS ULCERATIVE JEJUNOILEITIS WITH HYPOGAMMAGLOBULINEMIA.

(Eng.) Saxon, A.; Stevens, R. H.; Ashman, R. F.; Parker, N. H. (Univ. California Sch. Medicine, Los Angeles, CA 90024). *Clin. Immunol. Immunopathol.* 8(2):272-279; 1977.

Two patients with nongranulomatous ulcerative jejunoileitis with hypogammaglobulinemia were investigated to determine the nature of the immune defect responsible for hypogammaglobulinemia. Analysis of surface receptors revealed that both patients had an absolute number of bone marrow-derived (B) lymphocytes within the normal range. Both patients had an absolute and relative thymus-derived (T) lymphocytopenia. However, their T lymphocytes were capable of providing helper function for normal bone marrow-equivalent lymphocytes in immunoglobulin production. The B lymphocytes demonstrated an intrinsic defect in immunoglobulin production, which was not reversed by the addition of normal T lymphocytes. Neither patient had evidence of excess suppressor cells. Thus, both patients manifested similar dual immune defects, consisting of a qualitative B-lymphocyte block in immunoglobulin production and a quantitative T-lymphocyte deficiency.

2204 ISCHEMIC DISEASE OF THE SMALL BOWEL AND COLON ASSOCIATED WITH ORAL CONTRACEPTIVES.

(Eng.) Ghahremani, G. G.; Meyers, M. A.; Farman, J.; Port, R. B. (Evanston Hosp., 2650 Ridge Ave., Evanston, IL 60201). *Gastrointest. Radiol.* 2(3): 221-228; 1977.

The development of ischemic bowel disease in seven women taking oral contraceptives is reported. The ischemic changes, which involved the ileum in three patients and the colon in four patients, became reversible after conservative management and discontinuance of the agents. The radiologic features of ischemic disease in the small bowel and colon are remarkably similar. The characteristic changes are best visible on barium studies and include mucosal edema, superficial ulcerations, blunting of the valvulae and haustra, transverse ridging, marginal indentations or thumbprints due to submucosal edema and hemorrhage, and thickening of the intestinal wall causing separation of the adjacent loops. Evidence for spasm and irritability of the involved segments may also be seen at fluoroscopy. The subsequent disappearance of the ischemic changes in the above patients was the most important factor in establishing the diagnosis of reversible mesenteric vascular occlusion. It is suggested that conservative management with heparin, dextran infusion, and discontinuance of the contraceptive agent should be attempted in patients without signs of peritoneal irritation and radiographic findings of intestinal necrosis. The persistence or progression of the clinical and radiologic findings indicate the necessity for surgical intervention, because bowel infarction is often insidious when caused by venous occlusion.

2205 A PROSPECTIVE COMPARISON OF GASTRIC AND JEJUNOILEAL BYPASS PROCEDURES FOR MORBID OBESITY. (Eng.) Griffen, W. O., Jr.; Young, V. L.; Stevenson, C. C. (Univ. Kentucky Medical Center, 800 Rose St., Lexington, KY 40506). *Ann. Surg.* 186(4):500-509; 1977.

Gastric and jejunoileal bypass procedures for morbid obesity were compared in a randomized, prospective study of 59 patients. The gastric bypass was performed predominantly as a 90% gastric exclusion with a Roux-en-Y reconstitution. The jejunoileal bypass was an end-to-end anastomosis between 30 cm of jejunum and 25 cm of terminal ileum, the bypassed segment of small bowel being decompressed by an end-to-side ileocolostomy. There were 32 patients in the gastric group and 27 in the jejunoileal group. The two groups were comparable in age, preoperative weight, and height. There were no postoperative deaths, but the gastric bypass operation was associated with a slightly higher early complication rate (62.5% of the cases versus 48%), indicating that it is a more technically demanding procedure. Late sequelae were more prominent in the jejunoileal bypass group and included significant diarrhea in 56% and need for medication in 74%. Kidney stones and cholelithiasis also complicated the jejunoileal group and were not seen after gastric bypass. All patients showed fatty metamorphosis on the original liver biopsy. This had worsened in 75% of the jejunoileal group at 1 yr postoperatively, whereas it had improved or was stable in all patients in the gastric group. The results indicate that once the technique is perfected, gastric bypass is superior to jejunoileal bypass in the treatment of morbid obesity.

2206 CONGENITAL INTRINSIC DUODENAL OBSTRUCTION: A TWENTY-FIVE YEAR REVIEW. (Eng.) Wesley, J. R.; Mahour, G. H. (Children's Hosp. Los Angeles, Los Angeles, CA). *Surgery* 82(5):716-720; 1977.

Factors influencing the prognosis of congenital duodenal obstruction were assessed in 72 patients in whom this condition was diagnosed between 1951 and 1975. The survival rate was 55% during the first 15 yr of the study, but it increased to 88% during the last 10 yr. Factors important to this increased survival rate included earlier diagnosis and expeditious preoperative workup; expert administration of anesthesia; improved surgical technique with a greater awareness for common pitfalls, such as associated duodenal diaphragm or distal bowel atresia; frequent use of gastrostomy; use of parenteral nutrition; and better intensive nursing care.

SMALL INTESTINE

Malabsorption

2223 AMINO ACID AND PEPTIDE ABSORPTION IN PATIENTS WITH COELIAC DISEASE. (Eng.) Clark, M. L.; Fairclough, P. D.; Silk, D. B. A. (St. Bartholomew's Hosp., London, England). *Z. Ernaehrungswiss.* 20(Suppl.):32-37; 1977.

The absorption of amino acids and peptide was studied in adults to clarify the degree to which malabsorption of dietary protein contributes to the protein deficiency seen in some cases of celiac disease. Absorption of amino acids from perfused solutions was compared in eight normal subjects and seven patients with untreated celiac disease. The isotonic solutions contained the dipeptide glycyl-L-alanine (10 mM) or the same amino acids in the free form, 25 mM bicarbonate, and polyethylene glycol (PEG, 2.5 g/l), labeled with ^{14}C PEG (1 μCi/l). There was a significant reduction in absorption rates of both glycine and L-alanine from the mixture of free amino acids in the jejunum of celiacs when compared to the normal subjects ($p<0.02$). Mean total amino acid absorption in the celiac patients was reduced up to 40% of the control values. There was a significant ($p<0.001$) reduction in both glycine and L-alanine absorption from dipeptide solution in the celiacs. Comparable levels of free amino acids occurred in celiacs and normal subjects during jejunal perfusion of dipeptide, and there was no significant difference between luminal peptidase in both groups, indicating that back diffusion of free amino acids is increased in celiac disease. Ileal absorption of amino acids and peptide was normal in celiacs. The studies demonstrate that free amino acid and peptide absorption in the jejunum of celiac patients were impaired to the same degree. As total amino acid absorption was more rapid from dipeptide than from free amino acid solution, the use of peptide-containing elemental diets in celiac patients is recommended if rapidity of amino acid absorption is desirable.

2224 FACTORS RESPONSIBLE FOR WEIGHT LOSS IN TROPICAL SPRUE. (Eng.) Klipstein, F. A.; Corcino, J. J. (Univ. Rochester Medical Center, 601 Elmwood Ave., Rochester, NY 14642). *Am. J. Clin. Nutr.* 30(10):1703-1708; 1977.

The respective roles of reduced dietary intake and malabsorption in the pathogenesis of weight loss in 45 patients with chronic tropical sprue were evaluated. Dietary intake was significantly ($p<0.001$) less in the patients with tropical sprue (all of whom had anorexia due to deficiency of folate and/or vitamin B_{12}) than in 51 healthy Puerto Ricans. Weight loss was equally prominent in those patients with tropical sprue who had normal absorption of fat and protein as in those who had excessive fecal loss and reduced absorption of these nutrients.

Treatment of five sprue patients with folic acid or vitamin B_{12} for 2 weeks resulted in improved appetite and increase in dietary intake with weight gain in the absence of significant improvements in intestinal absorption. Treatment with p.o. tetracycline for a similar period of time in five other patients was not associated with vitamin repletion, return of appetite, or weight gain. These observations indicate that reduced dietary intake resulting from anorexia caused by vitamin deficiency is a significant, and sometimes the most important, factor in the pathogenesis of weight loss in persons with chronic tropical sprue.

2225 MALABSORPTION FOLLOWING RADIATION THERAPY. (Eng.) Burbige, E. J.; Tarder, G. L.; Belber, J. P. (Veterans Admin. Hosp., 150 Muir Rd., Martinez, CA 94553). *Am. J. Gastroenterol.* 67(6): 589-592; 1977.

The case is presented of a patient with transitional cell carcinoma of the bladder who developed diarrhea following radiotherapy and was treated symptomatically for 9 yr with the assumption that the diarrhea was secondary to radiation enteritis. Further evaluation, including endoscopic cholangiopancreatography, revealed pancreatic insufficiency with steatorrhea as the probable cause of the patient's diarrhea. Although temporally related to radiation therapy, the etiology of his pancreatic insufficiency remains speculative. All patients developing diarrhea and/or malabsorption following radiotherapy should be evaluated thoroughly for treatable causes.

LARGE INTESTINE

2235 ADYNAMIC BOWEL SYNDROME: REPORT OF A CASE WITH DISTURBANCE OF THE CHOLINERGIC INNERVATION. (Eng.) Puri, P.; Lake, B. D.; Nixon, H. H. (Hosp. Sick Children, London, England). *Gut* 18(9):754-759; 1977.

The case of an infant with adynamic bowel syndrome is described. Full thickness biopsies of the large bowel showed the presence of ganglion cells; no acetylcholinesterase-positive nerves in the lamina propria, submucosa, or among the smooth muscle cells of the circular and longitudinal muscle coats; and absence of the argyrophil plexus. Electron microscopy showed replacement of the normal axon bundle by vacuolated tracts with small round bodies, probably viral, in one area. Neuronal cytoplasm also showed similar vacuolation. The patient was successfully treated with an ascending colon loop colostomy, which was later transformed to an end ileostomy. It is suggested that the damage to the cholinergic innervation may be caused by a neurotoxic agent.

2236 ANGIODYSPLASIA OF THE RIGHT COLON: A CAUSE OF GASTROINTESTINAL BLEEDING. (Eng.)

Baum, S.; Athanasoulis, C. A.; Waltman, A. C.; Galdabini, J.; Schapiro, R. H.; Warshaw, A. L.; *et al.* (Hosp. Univ. Pennsylvania, 3400 Spruce St., Philadelphia, PA 19104). *Am. J. Roentgenol.* 129(5): 789-794; 1977.

Clinical experience with angiodysplasia of the right colon and cecum in 34 patients is presented, and the diagnostic importance of mesenteric arteriography in patients with chronic lower intestinal bleeding is emphasized. The patients had intermittent lower gastrointestinal bleeding and were diagnosed angiographically as having angiodysplasia of the cecum or right colon. Repeated barium and endoscopic examinations were negative. Right colectomy was carried out in 17 patients, who were followed postoperatively for up to 7 yr. Of these, four patients rebled, two of whom had angiographic evidence of related lesions involving other parts of the colon and terminal ileum. Silicone rubber injection and tissue-clearing techniques on the specimens facilitated the pathologic identification of these lesions. Histologically, they were seen to be dilated submucosal veins and arteries associated with areas of overlying mucosal thinning and occasional ulcerations. Although the pathogenesis of the lesion is unknown, they are probably acquired rather than congenital and result from chronic submucosal arteriovenous shunting secondary to mucosal ischemia. Of the 34 patients, 17 had a history of cardiac disease.

2237 FEASIBILITY OF FECAL OCCULT-BLOOD TESTING FOR DETECTION OF COLORECTAL NEOPLASIA: DEBITS AND CREDITS. (Eng.)

Winawer, S. J.; Miller, D. G.; Schottenfeld, D.; Leidner, S. D.; Sherlock, P.; Befler, B.; *et al.* (Memorial Sloan-Kettering Cancer Center, 1275 York Ave., New York, NY 10021). *Cancer* 40(5, Suppl.):2616-2619; 1977.

A screening program for colorectal cancer and adenomas was applied to 6,579 mostly asymptomatic men and women age 40 yr and older utilizing fecal occult blood testing followed by investigation of patients with positive slides by air-contrast barium enema and colonoscopy. A control population of 7,325 patients had sigmoidoscopy only and no occult blood testing. Approximately 1% of the patients had positive slides; most patients had only one or two positive slides. Approximately 50% of patients with positive slides had significant neoplastic lesions, including 23 patients with large adenomas and 7 patients with cancers. Pathological staging of cancer was more favorable in the screened asymptomatic group as compared with the control group. Neoplastic lesions seen on sigmoidoscopy in screened patients who had negative fecal occult blood tests included 2 cancers and 15 large adenomas. The false-negative results may have been due to conversion of initially positive slides to negative. Screening for colorectal cancer and adenomas with fecal occult blood testing appears to be a feasible approach with good patient compliance, and a manageable rate of positive slides productive of a high percentage of neoplastic lesions. The number of false-positives seems to be low.

2238 AGE-RELATED IMPAIRMENT OF TUMOR-ASSOCIATED LYMPHOCYTOTOXICITY IN PATIENTS WITH COLONIC ADENOCARCINOMA. (Eng.)

Goldrosen, M. H.; Rohrdanz, D.; Sabatino, B.; Burns, G. P.; Holyoke, E. D. (Roswell Park Memorial Inst., New York State Dept. Health, 666 Elm St., Buffalo, NY 14263). *Dis. Colon Rectum* 20(7):561-565; 1977.

The *in vitro* lymphocytotoxic responses of 27 preoperative patients with colon carcinoma and 61 healthy volunteers were correlated with age by linear regression analysis. The patients ranged in age from 34 to 88 yr (average 61.7), and the controls ranged from 16 to 88 yr (average 45.8). Cytotoxicity obtained with WBC from the cancer patients on the colonic cancer-cell line decreased with increasing age ($r=0.66$, $p \leq 0.01$). In contrast, cytotoxicity obtained with WBC from the controls on the same cell line did not correlate with age of the donor. Furthermore, the decline in cytolysis in the patient group could not be attributed to more extensive disease. These observations suggest that increasing age is an important factor associated with the decline in ability of colorectal cancer patients to generate a disease-related cytolytic reaction.

2239 ULTRASTRUCTURE OF THE "TRANSITIONAL" MUCOSA ADJACENT TO LARGE BOWEL CARCINOMA. (Eng.)

Riddell, R. H.; Levin, B. (Univ. Chicago Hosp. and Clinics, 950 East 59th St., Chicago, IL 60637). *Cancer* 40(5, Suppl.):2509-2522; 1977.

The transitional mucosa immediately adjacent to large bowel carcinoma was examined in 13 patients by scanning electron microscopy (SEM), and the results were correlated with those of transmission electron microscopy (TEM) and of light microscopy (LM). Marked abnormalities, including distortion and loss of the normal architecture, were present in this mucosa in nine patients. In all patients, the transitional mucosa was compared with two pieces of normal mucosa; in one patient, typical changes of transitional mucosa were found in this region. In the remaining patients, normal mucosa by SEM was found to consist of large deep furrows (primary crypts) as well as the crypts of Lieberkuhn (secondary crypts). The secondary crypt structure showed marked individual variation between patients, but one type was present in nine patients. It is uncertain whether this is a pattern with a high incidence in the general population, or whether patients with this type of mucosa are particularly predisposed to large bowel carcinoma. SEM may, therefore, play a part in identifying patients particularly likely to develop large bowel carcinoma.

2240 ANTIBIOTIC-INDUCED COLITIS: IMPLICATION OF A TOXIN NEUTRALISED BY Clostridium sordellii ANTITOXIN. (Eng.) Rifkin, G. D.; Fekety, F. R.; Silva, J., Jr.; Sack, R. B. (Univ. Hosp., Ann Arbor, MI 48109). *Lancet* 2(8048):1103-1106; 1977.

The feces of two patients with antibiotic-induced colitis were examined for the presence of toxin(s). A heat-labile toxin(s) was demonstrated in the stools of both patients. This toxin(s) was rapidly lethal to hamsters, increased the vascular permeability in rabbit skin, and was cytotoxic to cells in tissue culture. It was neutralized by *Clostridium sordellii* antitoxin but not by antitoxins prepared against other clostridia or against *Escherichia coli* and *Vibrio cholerae* toxins. These characteristics were identical to those of a toxin implicated in the etiology of antibiotic-induced colitis in the hamster. One patient improved rapidly after treatment with p.o. vancomycin, and at the same time the toxin disappeared from the stool.

2241 ISCHEMIC BOWEL DISEASE FOLLOWING BILATERAL NEPHRECTOMY OR RENAL TRANSPLANT. (Eng.) Margolis, D. M.; Etheredge, E. E.; Garza-Garza, R.; Hruska, K.; Anderson, C. B. (Barnes and Wahl Hosp., 4960 Audubon Ave., St. Louis, MO 63110). *Surgery* 82(5):667-673; 1977.

The case reports of five patients who developed pathologically proved ischemic bowel disease (IBD) following either renal transplantation or bilateral nephrectomy in preparation for transplantation during a 2-yr period are presented. This entity accounted for 42% of all major gastrointestinal complications in one transplant unit. Three patients presented with abdominal pain and ileus, and two patients developed massive lower gastrointestinal hemorrhage. All five patients had nonocclusive ischemic disease because obstruction of a major intestinal vessel could not be documented in any case. Each patient was treated with bowel resection, and three of the five patients survived. Although sepsis, shock, and large doses of immunosuppressive drugs have been implicated in predisposing such patients to IBD, these factors were not uniformly present in these cases. Blood volume redistribution with transient episodes of hypotension, especially during postoperative hemodialysis, may be significant. IBD in uremic patients can occur in the presence or absence of renal transplantation and may be the cause of massive intestinal hemorrhage in these individuals.

2242 VALUE OF A SINGLE FORCEPS BIOPSY OF COLONIC POLYPS. (Eng.) Livstone, E. M.; Troncale, F. J.; Sheahan, D. G. (Yale Univ. Sch. Medicine, 333 Cedar St., New Haven, CT 06510). *Gastroenterology* 73(6):1296-1298; 1977.

The accuracy of colonoscopic biopsies in predicting the histological diagnosis of colonic polyps removed at colonoscopy or at laparotomy was studied in 42 patients who were colonoscoped before the removal of 50 polyps. A single fractional biopsy was obtained from each lesion with the standard endoscopic biopsy forceps and was compared to the final histological diagnosis of each excised lesion. The fractional biopsy measured 2-3 mm in diameter in each case. Thirteen (26%) of the singular fractional biopsies did not demonstrate the significant histological features of the excised polyps. These tiny biopsies do not adequately represent the entire polyp. Moreover, the small size of the biopsy does not permit the study of the central submucosal area of the polyp stalk, the critical area for assessing invasive malignancy. Histological examination of a completely excised polyp is essential for accurate diagnosis and appropriate therapy.

Ulcerative Colitis

2287 SEVERE COLITIS IN CHILDREN AND ADOLESCENTS: DIAGNOSIS, COURSE, AND TREATMENT. (Eng.) Werlin, S. L.; Grand, R. J. (Harvard Medical Sch., Boston, MA). *Gastroenterology* 73(4, Part 1):828-832; 1977.

Nineteen children with severe colitis (14 with ulcerative colitis and 5 with Crohn's colitis) were analyzed according to newly established criteria. There were 8 boys and 11 girls (mean age 12.3 ± 3.8 yr), and duration of acute illness ranged from 2 to 56 days at the time of presentation. Six episodes responded to medical management within 12 days; one episode responded at 3 weeks, one at 4 weeks, and one had not responded when the patient was lost to follow-up. Extending the period of medical treatment beyond 12 days substantially increased morbidity and complications of therapy. No combination of criteria accurately predicted those patients who would respond to medical therapy alone. Ten episodes unresponsive to medical treatment required surgery for control of disease. Of nine patients initially treated with medical therapy alone, five required proctocolectomy for intractable disease in the 2-yr period after the severe attack; three others are doing poorly on a medical regimen (1.5-2.5 yr later), and only one is in remission (5 yr after the severe attack). The data demonstrate that 32% of children with severe colitis had a rapid response to medical management, but the remission achieved was short-lived. The majority of pediatric patients with severe colitis require surgery within 2 yr of the onset of the attack.

2288 THE DETECTION OF SEROLOGICAL FACTORS IN ACUTE ULCERATIVE COLITIS INDICATING A FAVOURABLE SHORT-TERM PROGNOSIS. (Eng.) Hunt, P. S.; Trotter, S. (Prince Henry's Hosp., St. Kilda Rd., Melbourne, Victoria 3004, Australia). *Aust. N.Z. J. Surg.* 46(1):88-91; 1976.

The significance of a possible interplay between autologous serum and lymphocytes in relation to the short-term natural history of acute ulcerative colitis was investigated. Large intestinal epithelial cells were obtained from surgical specimens and by biopsy at sigmoidoscopy from 16 patients with acute severe mucosal ulcerative colitis and 11 controls with normal large bowel mucosa. The ability of lymphocytes to release ^{51}Cr label from large intestinal epithelial cells was quantitatively assessed as percentage lymphocyte activity. The mean lymphocyte activity in 16 patients with acute ulcerative colitis on admission (88 ± 8%) was significantly greater than that in 11 normal subjects (16 ± 8%, $p<0.01$). In each study, samples of autologous serum were added to two reactions between lymphocytes and autologous large intestinal epithelial cells. The results in the seven patients who came to urgent colectomy differed significantly from those in the nine who responded to corticosteroids (44 ± 16% versus 12 ± 5%). When the serum of these patients was studied for immunofluorescent autoantibodies to normal human colonic mucosa, none of the seven patients treated by colectomy had detectable autoantibodies, as compared with three of the nine patients who responded to steroid treatment. The results support a previous suggestion that serological factors (i.e., anticolon antibodies) may account for the remissions and exacerbations of ulcerative colitis.

2289 FURTHER STUDIES OF SULPHASALAZINE METABOLISM IN THE TREATMENT OF ULCERATIVE COLITIS. (Eng.) Cowan, G. O.; Das, K. M.; Eastwood, M. A. (Western General Hosp., Edinburgh EH4 2XU, Scotland). *Br. Med. J.* 2(6094):1057-1059; 1977.

Sixty-four outpatients receiving maintenance treatment with sulphasalazine for ulcerative colitis were studied to relate disease activity to serum concentrations of sulphapyridine. Of 43 patients in remission, 32 had serum sulphapyridine levels >20 µg/ml. Ten of the 21 patients with active disease were taking inadequate doses of sulphasalazine, as indicated by low serum sulphapyridine levels, and of the remaining 11 patients who had serum levels >20 µg/ml, 9 had fecal stasis proximal to active distal colitis and went into remission when treated with hydrophilic colloid or bran and an unchanged sulphasalazine dosage. This suggests that to be effective the metabolites of sulphasalazine must be delivered in the feces to the lumen of the diseased distal segment of the colon. Because high serum concentrations of sulphapyridine produce side-effects, slow acetylators of sulphapyridine need lower doses of sulphasalazine. Estimations of serum sulphapyridine concentrations, as well as identifying the patient's acetylation phenotype, can also be useful in assessing whether the patient is taking the medication at regular intervals.

2290 CANCER IN COLITIS: ASSESSMENT OF THE INDIVIDUAL RISK BY CLINICAL AND HISTOLOGICAL CRITERIA. (Eng.) Lennard-Jones, J. E.; Morson, B. C.; Ritchie, J. K.; Shove, D. C.; Williams, C. B. (St. Mark's Hosp., City Rd., London ECIV 2PS, England). *Gastroenterology* 73(6):1280-1289; 1977.

To test the concept that histological examination of sequential biopsy specimens can detect patients with colitis who are at special risk of developing cancer, the cancer risk among 229 patients with extensive ulcerative colitis observed during January 1, 1966 to February 29, 1976 was correlated with the length of history and the histological findings in rectal and colonic biopsies. Five patients are known to have developed carcinoma. No carcinoma was observed in 578 patient-years of follow-up within 10 yr of onset of the colitis, but the risk in the second decade was approximately 1 in 200 patient-years and, in the third, 1 in 60 patient-years. Severe epithelial dysplasia was rare and was found in 32 biopsies from 13 patients. No carcinoma has occurred during the period of follow-up in patients without dysplasia. It was not possible to follow the development of dysplasia in sequential biopsies. Seven patients with consistent severe dysplasia on biopsy have been treated surgically; carcinoma confined to the bowel wall (Dukes' A) was found in four patients. A scheme of management for patients with extensive colitis, including regular rectal and colonic biopsies, is proposed. The results suggest that such a program will isolate a small group of patients who require surgical treatment for established precancerous change or carcinoma with a high likelihood of cure.

2291 EARLY DETECTION AND PREVENTION OF CARCINOMA OF THE COLON IN PATIENTS WITH ULCERATIVE COLITIS. (Eng.) Dobbins, W. O., III; Stock, M.; Ginsberg, A. L. (2150 Pennsylvania Ave., N.W., Washington, DC 20037). *Cancer* 40(5, Suppl.):2542-2548; 1977.

The available methods for the early detection and prevention of colonic carcinoma in patients with ulcerative colitis are reviewed. These methods include detection of precancer (carcinoma *in situ*) in rectal and colonic biopsies, with and without immunoperoxidase staining for carcinoembryonic antigen; detection of persistently elevated serum carcinoembryonic antigen; roentgenologic detection; colonoscopic detection; cytologic detection; and simple recommendation of total colectomy in all patients with continuously active, extensive colitis after 10 yr of disease. Of the methods available, only detection of precancer in rectal and colonic biopsies holds promise for the early detection of colonic carcinoma, and there are many pitfalls with this method. Precancer, when analyzed in total colectomies, is absent in 12% of patients with carcinoma complicating ulcerative colitis and is found in the rectum in only 66% of these patients. Thirteen percent of patients with severe ulcerative colitis requiring colectomy have precancer in the absence of cancer. Precancer, when analyzed in rectal biopsies of patients with ulcerative colitis, is found in 5.7% of the patients. One study showed that 32% of those patients with precancer in rectal biopsy had colonic carcinoma, while two-thirds of these patients did not have colonic cancer. The role of colonoscopy at regular intervals with the collection of multiple biopsies throughout the colon is currently being evaluated in hopes that this method will more accurately and consistently permit early detection of precancer and cancer in patients with ulcerative colitis of 10 or more years' duration.

2292 HUMORAL IMMUNE SYSTEM IN INFLAMMATORY BOWEL DISEASE: I. COMPLEMENT LEVELS. (Eng.) Hodgson, H. J. F.; Potter, B. J.; Jewell, D. P. (Royal Free Hosp., London, England). *Gut* 18(9):749-753; 1977.

Serum levels of complement components Clq, C4, C3, and Properdin factor B, from the classical and alternative pathways of complement activation, were estimated in 93 patients with ulcerative colitis and 66 patients with Crohn's disease. C3, factor B, and, to some extent, C4 concentrations all increased when the disease was active. In remission, the levels of these components did not differ from those in 31 hospital control patients. There was no evidence for the preferential consumption of the proteins of either pathway of activation, even in those patients with evidence of circulating immune complexes.

2293 ULCERATIVE COLITIS, ANTI-B LYMPHOCYTOTOXIN AND ANTICOLON ANTIBODIES IN A PATIENT WITH HUMORAL IMMUNODEFICIENCY: DIGESTIVE AND IMMUNOLOGIC INVESTIGATIONS [Abstract]. (Eng.) PANCREAS

2297 NEEDLE ASPIRATION BIOPSY OF THE PANCREAS AT LAPAROTOMY. (Eng.) Kline, T. S.; Abramson, J.; Goldstein, F.; Neal, H. (Lankenau Hosp., Lancaster and City Line Ave., Philadelphia, PA 19151). *Am. J. Gastroenterol.* 68(1):30-33; 1977.

Six years of experience with thin needle aspiration biopsies obtained from the pancreas during laparotomy on 56 patients is presented. An 18- to 22-gauge spinal needle attached to a disposable syringe was used. The specimens were fixed immediately and stained according to the method of Papanicolaou. The accuracy was 94% for 36 carcinomas and there were no false-positives in the 20 benign lesions. In this series, 21/56 had rapid diagnosis by this method during surgery and in 4, the Whipple operation was performed successfully. The safety, ease of interpretation, and high accuracy of this method make this an extremely useful procedure.

2298 PANCREATIC CANCER SCREENING: ANALYSIS OF THE PROBLEM AND THE ROLE OF RADIONUCLIDE IMAGING. (Eng.) Hall, T. J.; Cooper, M.; Hughes, R. G.; Levin, B.; Skinner, D. B.; Moossa, A. R. (Univ. Chicago, Pritzker Sch. Medicine, Chicago, IL). *Am. J. Surg.* 134(5):544-548; 1977.

The clinical, surgical, and pathologic findings in a 5-yr prospective study of 192 patients referred with a high probability of pancreatic cancer are reported. The requirements of any pancreatic imaging procedure were defined as its ability to distinguish a normal pancreas from pancreatic cancer or chronic pancreatitis and the capability of detecting tumors <5 cm in diameter. There was a 47% incidence of pancreatic disease (27% pancreatic cancer and 20% chronic pancreatitis). Prospective radionuclide imaging (^{75}Se-selenomethionine) was of little clinical value in this patient population; it was neither specific nor sensitive to pancreatic cancer or chronic pancreatitis. Preliminary data with longitudinal multiplane emission tomography show an improved diagnostic accuracy and the ability to detect resectable tumors, but its efficacy needs to be prospectively compared with other screening tests on a carefully defined patient population.

2299 THE PROSPECTIVE EVALUATION OF TUMOUR-ASSOCIATED ANTIGENS FOR THE EARLY DIAGNOSIS OF PANCREATIC CANCER. (Eng.) Wood, R. A. B.; Moossa, A. R. (Ninewells Hosp. and Medical Sch., Dundee, Scotland). *Br. J. Surg.* 64(10):718-720; 1977.

In a study of the validity of assaying tumor-associated antigens for the early diagnosis of pancreatic cancer, blood was obtained from 136 unselected patients suspected of having a major intra-abdominal pathological condition and was stored as serum. A definitive histological diagnosis was made in all cases, usually by laparotomy. Thirty-eight patients had pancreatic cancer. The serum was analyzed with coded samples for carcinoembryonic antigen, alpha fetoprotein, and pancreatic oncofetal antigen, and all recorded levels above the upper limit of normal for that test were taken as positive results (≥ 5.0 ng/ml and ≥ 40 ng/ml for carcinoembryonic antigen and alpha fetoprotein, resp.; oncofetal antigen was graded on a 0 to +++ scale, with $\geq$+ taken as a positive result). The results were analyzed to give the predictive value of a positive test and of a negative test for each antigen. A negative pancreatic oncofetal antigen test was found to be useful in excluding a diagnosis of pancreatic cancer; it gave a negative result in 94% of patients without pancreatic cancer.

2300 LOCALIZATION OF GLUCAGONOMAS BY CATHETERIZATION OF THE PANCREATIC VEINS AND WITH GLUCAGON ASSAY. (Eng.) Ingemansson, S.; Holst, J.; Larsson, L. I.; Lunderquist, A. (Bispebjerg Hosp., Copenhagen, Denmark). *Surg. Gynecol. Obstet.* 145 (4):509-516; 1977.

Experiments were carried out in two patients with glucagonomas to determine whether glucagonomas could be detected preoperatively by determining differences in arteriovenous glucagon. Percutaneous transhepatic puncture of the portal vein and catheterization of the pancreatic veins were performed simultaneously with catheterization of the inferior vena cava and abdominal aorta. Blood samples obtained from the vena cava, aorta, and portal branches were assayed for glucagon, using an indirect immunohistochemical method. In both patients, significant arteriovenous glucagon differences allowed preoperative localization of the tumors; in the celiac artery, hepatic vein, and main portal vein, the decrease in glucagon levels from the preoperative to postoperative state was significant ($p<0.001$). A comparison with other localization techniques, such as scintiscan, ultrasound, arteriography, and pancreatic phlebography, showed the present method to be superior. Postoperatively, the same investigations were performed revealing arterial and venous glucagon levels comparable to the levels measured in a reference group of three patients without glucagonomas. The triple catheterization technique is advocated for all patients with clinical and laboratory findings that suggest pancreatic endocrine tumors.

2301 BILE SALT KINETICS IN CYSTIC FIBROSIS: INFLUENCE OF PANCREATIC ENZYME REPLACEMENT. (Eng.) Watkins, J. B.; Tercyak, A. M.; Szczepanik, P.; Klein, P. D. (Children's Hosp. Medical Center, 300 Longwood Ave., Boston, MA 02115). *Gastroenterology* 73(5):1023-1028; 1977.

Bile acid kinetics were investigated by a stable isotope-dilution technique in six children (ages 3.5 months to 4.5 yr) with previously untreated cystic fibrosis. All patients had malabsorption, normal intestinal mucosal function (as judged by glucose absorption), intestinal histology, disaccharidase levels, and normally functioning gallbladders. The children were maintained on a constant diet throughout the study period; fat intake averaged 4.2 g/kg/day. Before the administration of pancreatic enzyme replacement, fat excretion equalled 50 ± 4% of intake and was reduced to 20 ± 1.0% of intake after therapy. The total bile acid pool size nearly doubled during enzyme replacement from 379 ± 32 µmol/kg to 620 ± 36 µmol/kg with secondary bile acids comprising 57% of the total pool before therapy and 40% after therapy. Total bile acid synthesis changed little with therapy, equaling 139 ± 17 μmol/kg/day (total 602 ± 109 mg/day) without enzyme replacement and 125 ± 19 μmol/kg/day (total 470 ± 86 mg/day) with enzyme replacement. This result was confirmed by the fecal excretion of bile acids: 545 ± 166 mg of bile acid/day were excreted without enzymes as compared to 513 ± 146 mg/day with enzymes. After therapy, the fractional turnover rate of the bile acid pool was reduced from 0.602 ± 0.05/day to 0.233 ± 0.03/day for cholic acid and from 0.696 ± 0.09/day to 0.39 ± 0.04/day for chenodeoxycholic acid. These data indicate that both primary and secondary bile acids are conserved within the enterohepatic circulation during enzyme therapy, and that the mechanism for the regulation of hepatic bile acid synthesis is intact in cystic fibrosis. However, the demonstration that large amounts of bile acid continue to be excreted during therapy suggests that interruption of the enterohepatic circulation continues and that deficiencies of the intraluminal phase may persist during enzyme therapy in this disease.

2302 ABNORMAL BILIARY LIPID COMPOSITION IN CYSTIC FIBROSIS: EFFECT OF PANCREATIC ENZYMES. (Eng.) Roy, C. C.; Weber, A. M.; Morin, C. L.; Combes, J. C.; Nussle, D.; Megevand, A.; *et al.* (Hopital Ste. Justine, 3175 Ste. Catherine Rd., Montreal, Quebec H3T 1C5, Canada). *N. Engl. J. Med.* 297(24):1301-1305; 1977.

Because of the increased incidence of gallstones in cystic fibrosis, biliary lipid composition was compared in 26 patients with cystic fibrosis, 7 children with cholelithiasis but without cystic-fibrosis, and 13 controls. Eighteen of the cystic fibrosis patients had cholecystograms; only one had gallstones. In 14 patients with cystic fibrosis who had stopped taking pancreatic enzymes for 1 week, the mean molar percentage of lipid composition accounted for by cholesterol (16.3 ± 2.9%) and the saturation index (2.0 ± 0.3) were comparable to values of the cholelithiasis group and higher ($p<0.01$) than those of controls. In 12 patients with cystic fibrosis taking pancreatic enzymes, the mean molar percentage of cholesterol (8.6 ± 1.7%) and the saturation index (1.0 ± 0.1) did not differ from those of controls; in cystic fibrosis there was a preponderance of cholic over chenodeoxycholic acid both off (1.7 ± 0.2%) and on (1.9 ± 0.3%) therapy as compared to the cholelithiasis (0.7 ± 0.1%) and control (0.8 ± 0.0%) groups. The glycine/taurine ratio of conjugated bile acids was lower in enzyme-treated patients with cystic fibrosis (3.7 ± 0.6) than in patients off treatment (6.4 ± 1.0), but was higher ($p<0.01$) than in controls (1.8 ± 0.2). Bile is lithogenic in untreated cystic fibrosis patients, but responds to pancreatic enzymes.

2303 INFLUENCE OF LYOPHILIZED TOTAL PANCREAS ON PLASMA LIPIDS AND ON FAT ABSORPTION IN CYSTIC FIBROSIS. (Eng.) Malmendier, C. L.; Van den Bergen, C. J.; Baran, D. (St. Pierre Univ. Hosp., 322 Rue Haute, 1000 Brussels, Belgium). *Helv. Paediatr. Acta* 32(2):115-128; 1977.

The effects of a lyophilized pancreatic powder preparation on the plasma lipid concentration, on the fatty acid composition of neutral lipids (NL), triglycerides (TG), cholesteryl esters (CE), and phospholipids (PL), and on the coefficient of fat absorption were studied in 31 children with cystic fibrosis (CF) and pancreatic insufficiency and in 27 controls to evaluate the treatment. The children were subdivided into three groups according to their age, and lipids were studied before and after the treatment. The CF children had marked decreases in total lipids, cholesterol, TG, and PL content. Treatment with lyophilized pancreas normalized the mean values of PL but only slightly increased total cholesterol. Polyunsaturated fatty acids (PUFA) increased in NL, TG, and PL in normal children, whereas saturated (C16:0 and C18:0) and mono-unsaturated (C16:1 and C18:1) fatty acids increased in CF children; differences were more pronounced in NL and CE than in PL. The arachidonic/linoleic ratio was normal in CF children, suggesting no abnormality in desaturation of fatty acids at this step in metabolism. Treatment with total pancreas extract raised PUFA content (C18:2 and C20:4) in NL, CE, and TG in CF children. The mean fat absorption coefficient was 94.8 ± 1.5% in normal children as compared to 65 ± 7.6% in CF children ($p<0.001$). Treatment with lyophilized pancreas extract increased this coefficient in CF children to 82.5 ± 5.6% ($p<0.01$). In conclusion, treatment of CF patients with lyophilized pancreas normalized PL plasma concentration but corrected only to a limited degree cholesterol concentration and PUFA percentage. It is suggested that the significant correlation found between the fat absorption coefficient and PUFA percentage in NL of CF children may be used as an index of the stage of malabsorption.

2304 PANCREAS DIVISUM: ITS ASSOCIATION WITH PANCREATITIS. (Eng.) Gregg, J. A. (110 Francis St., Boston, MA 02215). *Am. J. Surg.* 134(5):539-543; 1977.

Experience with 33 patients with pancreas divisum studied by endoscopic retrograde cholangiopancreatography (ERCP) are described. Pancreatitis was present in 15 patients, and another 11 had recurrent episodes of pain typical of pancreatitis. The major papilla was cannulated in all patients, but the duct of Wirsung was opacified in only 28 and showed changes of pancreatitis in 1. Attempts were made to cannulate the minor papilla in 15 of the 33 patients and were successful in 4. The duct of Santorini showed typical changes of pancreatitis in one case. One patient had pancreatic cancer, and the duct of Wirsung demonstrated only nonspecific abnormalities. In only two cases was pancreatitis due to alcohol abuse. The high incidence of pancreatitis and pancreatic-like pain in patients with pancreas divisum may be due to the very small ampulla of the duct of Santorini, which in these patients drains the majority of the pancreas, creating a marked relative stenosis of the ampulla. Surgery for relief of pain was required in five patients. The operation of choice, when pancreatitis involves the dorsal pancreas, appears to be distal resection with drainage.

2305 COMPARATIVE EFFECTS OF ANTACIDS, CIMETIDINE AND ENTERIC COATING ON THE THERAPEUTIC RESPONSE TO ORAL ENZYMES IN SEVERE PANCREATIC INSUFFICIENCY. (Eng.) Regan, P. T.; Malagelada, J. R.; DiMagno, E. P.; Glanzman, S. L.; Go, V. L. W. (Mayo Clinic and Mayo Foundation, Rochester, MN 55901). *N. Engl. J. Med.* 297(16):854-858; 1977.
